

**DESY Summer Student Program**  
**19./20. Aug 2009**  
**Hamburg**

# Physics in pp collisions

LHC, machine, detectors, physics

Johannes Haller  
(Universität Hamburg)

Yesterday: ● **Motivation/Introduction:** open questions in particle physics

● **Hadron Collider Basics**

● **Detectors:** ATLAS and CMS

Today: ● **Physics:** Existing results and prospects for the LHC

■ SM physics:

- ▶ W and Z production at hadron colliders
- ▶ Top quark production at hadron colliders
- ▶ Search for the Standard Model Higgs boson

■ Search for physics beyond the Standard Model:

- ▶ SUSY
- ▶ (GUT → Leptoquarks)

# Overview of physics process in pp collisions

- At the LHC and in pp collisions in general a wide range of physics processes is accessible
  - High centre-of-mass energy and high luminosity allows to explore completely new regime
  - Discoveries expected
- Due to huge QCD background (jets), leptons (electron, muons) must be used to select electroweak processes and events of New Physics
- Note: at the LHC very high rates are expected for
  - Jets (of course)
  - W/Z
  - Top-pair production  $\rightarrow$  "top factory"

- Indirect determination of  $W$  and top quark mass possible from comparison of precise experimental results with higher order calculations
- Comparison with direct measurements are a crucial consistency test of the Standard Model

- Try to measure the mass of  $W$  and top as precisely as possible
- Most of the information comes from hadron colliders
  - Number of  $W \rightarrow l\nu$  produced at Tevatron ( $6 \text{ fb}^{-1}$ ): 9 Mio events
  - Number of  $W \rightarrow l\nu$  expected for LHC ( $10 \text{ fb}^{-1}$ ): 60 Mio events

## History: Discoveries in the electroweak sector of the SM:

- Discovery of Neutral Current (Gargamelle, bubble chamber in neutrino beam, **1973**)  
→  $m_W \sim 80 \text{ GeV}$ ,  $m_Z \sim 90 \text{ GeV}$
- Rubbia+van der Meer: transformation of the CERN 450 GeV Super-p-synchrotron into a Proton-Anti-Proton collider (SppS):  $\sim 50 \text{ Events/mb}\cdot\text{sec}$ 
  - two detectors: UA1 und UA2
  - **1983** discovery of  $W^\pm$  und  $Z^0$
- **1989-2000**: Measurements at LEP
- **now**: 1.96 TeV Tevatron (FNAL-Chicago)
- **Starting now**:  $pp$  @14 TeV at LHC (CERN-Geneva)

## Production mechanisms:

- if  $x_1 \neq x_2 \rightarrow p_z$  of W is unknown (long.)  
→ interesting variable in hadron collisions is  $p_T$

## Decay of the W:

- W couples to all left-handed fermions
- Expect the decay ratios:

$$W \rightarrow e^+ \nu_e, \mu^+ \nu_\mu, \tau^+ \nu_\tau, u \bar{d}', c \bar{s}'$$

$$1 : 1 : 1 : 3 : 3$$

- exp.:  $\text{BR}(e\nu) = \text{BR}(\mu\nu) = \text{BR}(\tau\nu) = 10.7\%$
- Corrections from hadronisation

• W identification:

$$W^\pm \rightarrow e^\pm + \nu_e \quad W^\pm \rightarrow \mu^\pm + \nu_\mu$$

- Lepton with high  $p_T$  and  $p_{T,miss}$  from  $\nu$ , "back to back"

Schematic event display:

UA1-Detektor:

- Drift chamber 2x2x6 m<sup>3</sup>
- B-field: 0.7 Tesla
- em. Calorimeter
- Muon-system

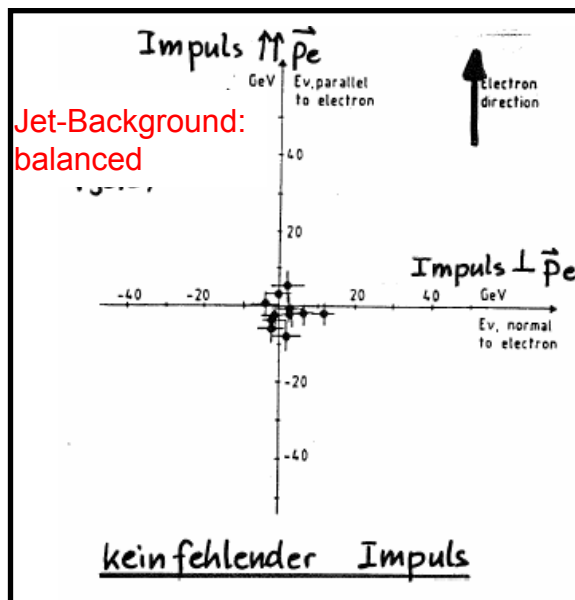

# Discovery of W and Z bosons

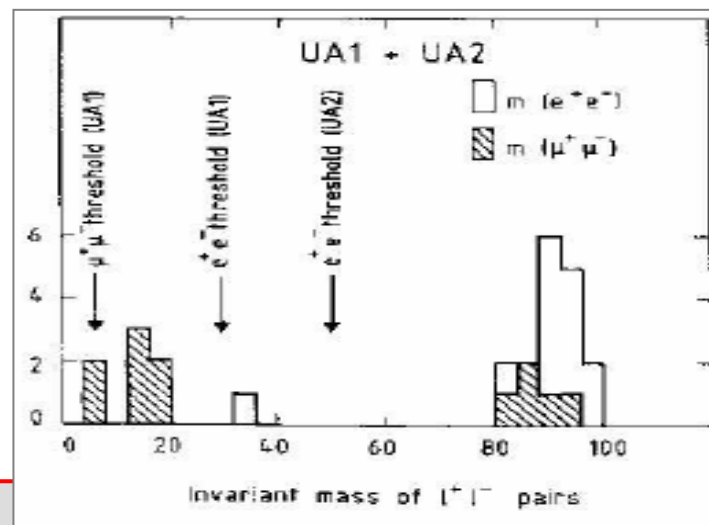

• **UA1/UA2-results:**

- **Jan.1983:** 7 Events  $W \rightarrow e\nu \rightarrow M_W = 81 \pm 5 \text{ GeV}$
- **July 1983:** 22 Events (UA1 +UA2)  $Z^0 \rightarrow e^+e^-/\mu^+\mu^- \rightarrow M_Z = 90 \text{ GeV}$  ( $\sigma \times \Gamma \sim 10x$  smaller than W! But clean signatures, since no missing  $\nu$ .)

• **Typical  $Z^0$ -Event in UA1:**

Invariant Di-Lepton-Mass:

- **1984: Nobel Prize for S. van der Meer and C. Rubbia**

- Mass of the W boson can be determined from  $p_{Te}$  distribution of the electrons:

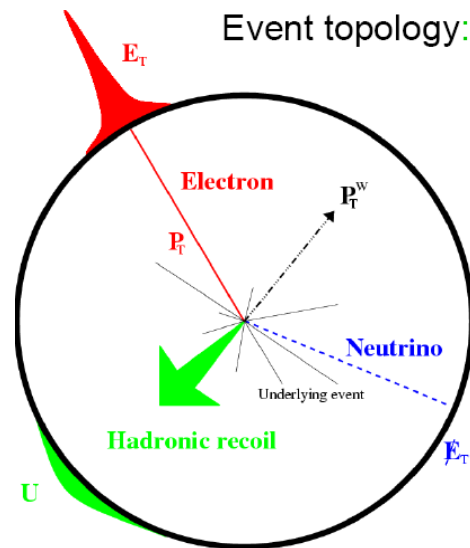

- "Jacobean-Peak"
- $p_{Te} < M_W/2$
- but sensitive to possible  $p_T$  of W (HO QCD effects)

- Less sensitive to this effect: „transverse mass“:

$$m_T = \sqrt{|p_T^l|^2 + |p_T^\nu|^2 - (\vec{p}_T^l + \vec{p}_T^\nu)^2}$$

- Corresponds to invariant mass visible in transverse plane
- $M_T < M_W$

## TeVatron

## D0

LAr-calorimeter (high granularity)

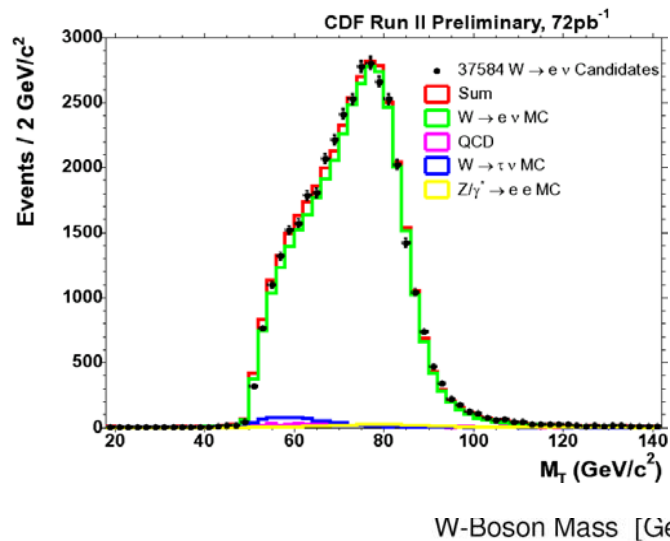

In run I: no magnetic field

- Proton **Antiproton** Collider
- Two experiments: CDF, D0
- 1992-1996: Run I  $\sqrt{s}=1.8$  TeV
  - $\int L dt=125\text{pb}^{-1}$
- 1996-2001: Upgrade of the machine:
  - New Injector, Anti-Proton-Recycler
  - Higher luminosity, higher rates
- Since March 2001: Run II  $\sqrt{s}=1.96$  TeV
  - Up to now  $\int L dt=6\text{fb}^{-1}$
  - Plan: operation until 2011(?)

## Studies ongoing at the Tevatron.

- Determination of  $M_W$  from comparison of  $M_T$  simulation for various  $M_W$  with data
- Crucial: accuracy of the simulation!

## Combination with results from LEP2

LHC: same techniques as Tevatron, aim:  $\Delta m_W = 15$  MeV

- $M_{top}$  is a very important parameter of the SM
- From the current colliders the top quark can only be produced at Tevatron
- Production via strong interaction:

- Increase of gluon induced processes with  $\sqrt{s}$  due to and proton structure  $\sqrt{\hat{s}} = \sqrt{x_1 x_2 s}$
- Lower x values  $\rightarrow$  more gluons

	Run 1	Run II	LHC
	1.8 TeV	1.96 TeV	14 TeV
qq	90%	85%	5%
gg	10%	15%	95%
$\sigma$ (pb)	5 pb	7 pb	600 pb

100 GeV: LHC  $x \sim 0.007$  Tevatron 0.05  
 5 TeV: LHC  $x \sim 0.36$  Tevatron --

- Much higher cross sections at the LHC: “top factory”

- Production at Hadron colliders: **strong interaction**
- Decay: **weak interaction**
- Remember: in matrix element of weak quark decays the corresponding CKM matrix element appears

$$-\frac{ig}{\sqrt{2}} \bar{t} \gamma^\mu \frac{1}{2} (1 - \gamma^5) V_{tb} b W_\mu$$

$$\begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} \sim 0.974 & \sim 0.23 & \sim 0.003 \\ \sim 0.022 & \sim 0.974 & \sim 0.04 \\ 0.004 - 0.01 & 0.04 & \sim 1 \end{pmatrix}$$

- Decays  $t \rightarrow W + s$  ( $\bar{t} \rightarrow Ws^-$ ) and  $t \rightarrow W + d$  ( $\bar{t} \rightarrow Wd^-$ ) (allowed in principle) are strongly suppressed
- BR ( $t \rightarrow Wb$ ) = 100%

- Top is so heavy that it decays before hadronisation  $\tau_{\text{top}} = 4 \cdot 10^{-25} \text{s}$  (due to the large phase space available)
  - There are no bound states with top flavour ("toponium").
  - In top physics a free quark is studied.

### 3 event categories:

#### 1) „Dileptons“

- + easy to identify (e and  $\mu$ )
- small cross section (fraction for e and  $\mu$  is only 5 %)
- missing energy from two neutrinos

#### 2) „Lepton+Jets“

- + Cross section larger:  $\sim 30\%$
- + Only one neutrino to be considered in the reconstruction

#### 3) purely hadronic

- Hard to reconstruct (QCD background), not covered here.

Note: all events contain 2 b-jets

- Topologies of  $t\bar{t}$  events are determined by W- decay

Top Pair Decay Channels

3/9	$c\bar{s}$	electron+jets	muon+jets	tau+jets	all-hadronic	
3/9	$u\bar{d}$					
1/9, 1/9, 1/9	$\tau^+$	$e\tau$	$\mu\tau$	$\tau\tau$		tau+jets
1/9	$\mu^-$	$e\mu$	$e\tau$	$\mu\tau$		muon+jets
1/9	$e^-$	$e\mu$	$e\tau$			electron+jets
W decay	$e^+$	$\mu^+$	$\tau^+$	$u\bar{d}$	$c\bar{s}$	
	1/9	1/9	1/9	3/9	3/9	

- All of the aforementioned topologies contain two jets from b quarks

## Side remark: „B-Tagging“:

1) Search for secondary vertex  $B^0: m = 5.3 \text{ GeV}, \tau = 1.6 \text{ ps}$

– B mesons decay after

$$l = \beta \gamma c \tau = \frac{E}{m} c \tau \sim 1 \text{ mm}$$

Good resolution of Si- detectors needed

2) Search for leptons in jets from semileptonic b-decay:

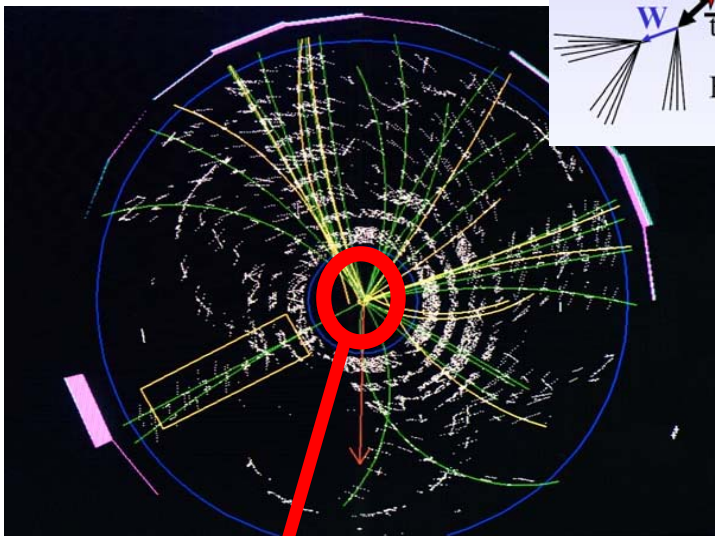

- $b \rightarrow l \nu c$  (BR  $\sim 20\%$ )
- $b \rightarrow c \rightarrow l \nu s$  (BR  $\sim 20\%$ )

# Example top candidates from TeVatron

tt- candidate  
(lepton+jets):

- 2 normal jets
- 2 b-jets
- lepton,
- Missing energy

$l_1 = 4.5 \text{ mm}$   
 $l_2 = 2.2 \text{ mm}$

tt- candidate (Di-Lepton)

Object	$p_T$ (GeV)	$\eta$	$\phi$
electron	65.097	-0.539	0.853
muon	48.148	0.565	3.400
jet 1	192.272	-0.183	6.027
jet 2	80.943	-0.425	4.080
$\cancel{E}_T$	156.022		2.630

- **Best channel: Lepton-Jets**
  - Dileptons: direct measurements impossible due to two missing  $\nu$
  - Purely hadronic: bad ratio of signal to background
- Event selection:
  - 1 hard charged lepton (e oder  $\mu$ )
  - $E_{T\text{miss}} > 20 \text{ GeV}$
  - $\geq 4$  hard jets (two with b-tag)
- **Unclear mapping of observed jets to quarks in final state:**  $\rightarrow$  24 possibilities
- For all possible mappings a kinematic fit is performed

- For each event the invariant mass of the  $bl\nu$ -system is calculated; then the measured momentums of the final state object are varied within their experimental uncertainties.
- Other varied parameter of the fit is  $m_{\text{top}}^{\text{reco}}$ .
- $\Delta\chi^2$  is minimized, ie. the free parameters of the fit (momenta and  $m_{\text{top}}^{\text{reco}}$ ) are determined such that they best fit the measurement and the hypothesis.
- Chosen is the mapping which leads to the minimal  $\Delta\chi^2$  after minimization
- $m_{\text{top}}^{\text{reco}}$  is regarded as the observed top mass for this event

$$\chi^2 = \sum_{i=\ell, 4\text{jets}} \frac{(p_T^{i,\text{fit}} - p_T^{i,\text{meas}})^2}{\sigma_i^2} + \sum_{j=x,y} \frac{(p_j^{UE,\text{fit}} - p_j^{UE,\text{meas}})^2}{\sigma_j^2} + \frac{(M_{\ell\nu} - M_W)^2}{\Gamma_W^2} + \frac{(M_{jj} - M_W)^2}{\Gamma_W^2} + \frac{(M_{b\ell\nu} - m_t^{\text{reco}})^2}{\Gamma_t^2} + \frac{(M_{bjj} - m_t^{\text{reco}})^2}{\Gamma_t^2},$$

- Determination of the top mass from comparison with simulation for various  $m_{\text{top}}$  values  $\rightarrow$  “templates”

CDF:

680 pb<sup>-1</sup>

- There are other methods which are used at the TeVatron to determine  $m_{\text{top}}$
- World average today:  $173.1 \pm 1.3$  GeV
- Expectation for the LHC for 10 fb<sup>-1</sup>:  $< \sim 1$  GeV

- Remember: indirect prediction of a light SM Higgs boson

- SM predicts: the Higgs couples to SM particles proportional to their masses
- consequence: Higgs decays into the heaviest particle which is kinematically accessible
- **Branching ratios of the Higgs:**

- Interesting and relevant for the searches at the LHC:
  - $100 < M_H < 140$  GeV:  $\gamma\gamma$ -decay possible
  - Not possible on tree level since photon is mass-less
  - But: possible via fermion loops
  - small BR, but almost no background in pp

- similar:
  - $H \rightarrow gg$ ,  $gg \rightarrow H$
  - Top quark loop

# Search for the Higgs in $e^+e^-$ collisions

- in  $e^+e^-$  Higgs bosons produced by „Higgs-radiation“ ( $Z \rightarrow ZH$ ):

$\sigma(\sqrt{s})$ : „large“ at Z-resonance and if  $\sqrt{s} > m_Z + m_H$  (kin. threshold)

## Example: Search for a Higgs signal in LEP2 data:

- $E_{\text{max}} \sim 209$  GeV  
 $\rightarrow$  sensitivity  $\sim m_H < 118$  GeV
- 4 Event classes:**

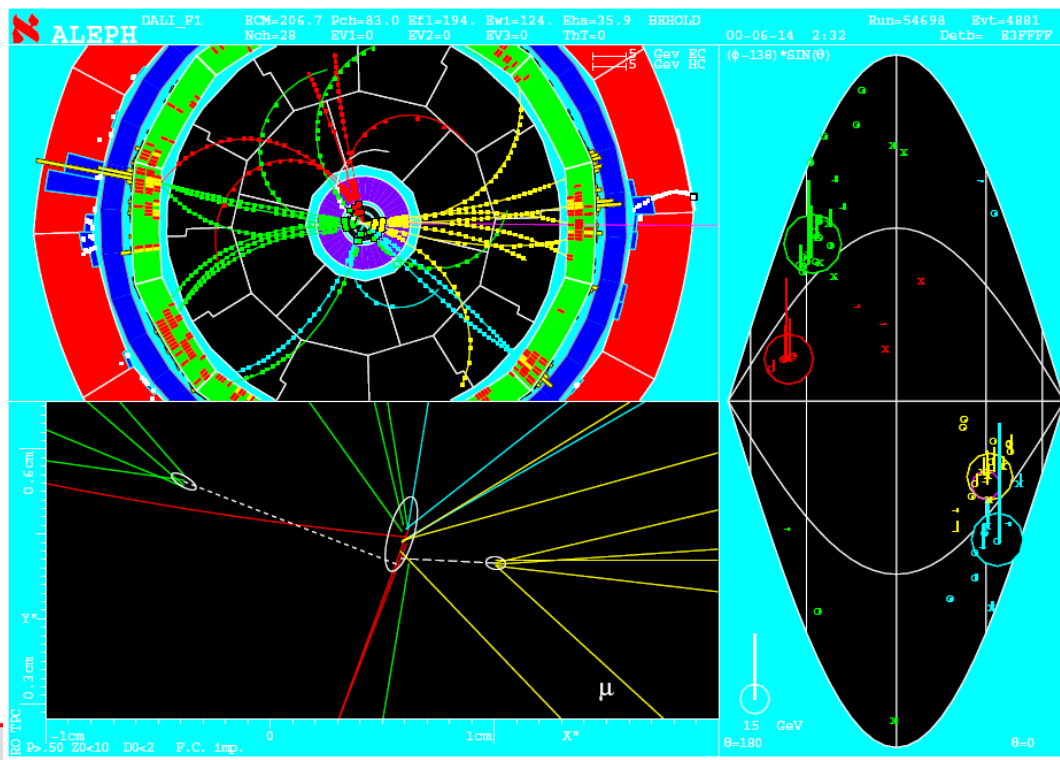

<p>Four jets, 60%</p> <p><math>H \rightarrow b\bar{b}, Z \rightarrow q\bar{q}</math></p>	<p>Missing energy, 18%</p> <p><math>H \rightarrow b\bar{b}, Z \rightarrow \nu\bar{\nu}</math></p>
<p>Leptonic, 6%</p> <p><math>H \rightarrow b\bar{b}, Z \rightarrow \ell^+\ell^-</math></p>	<p>Tau channels, 9%</p> <p><math>H \rightarrow b\bar{b}(\tau^+\tau^-), Z \rightarrow \tau^+\tau^-(q\bar{q})</math></p>

- No Higgs signal in data

- 2000: just before LEP shut-down: signal mainly driven by ALEPH events
- After complete reconstruction:  $1.7 \sigma$  deviation at  $M_H=115$  GeV.
- **Final LEP result:  $m_H > 114.4$  GeV with 95% CL.**

ALEPH event in  $q\bar{q}b\bar{b}$  channel:

## Possible production processes:

### gg fusion

### H-radiation, associated production

- Most important at TeVatron: gg fusion and H radiation
- Note: cross sections much larger at the LHC
  - E.g  $gg \rightarrow H$ :  $\sim 70$ - $80$  times (reason again: gluon density in proton)

### vector boson fusion

### „assoc. prod.“ with heavy Q

- production@TeVatron: **gg**→**H** or **WH, ZH**
- Most promising searches in main decay channels: **H**→**bb**<sup>-</sup> ( $m_H < \sim 135$  GeV) and **H**→**WW** ( $m_H > \sim 135$  GeV)
- H→bb<sup>-</sup> not usable in gg→H due to QCD background, only usable in associate production.

### Higgs- Signaturen am TeVatron:

➤  $m_H < \sim 135$  GeV:

WH → lν bb

ZH → ll bb

ZH → νν bb

➤  $m_H > \sim 135$  GeV:

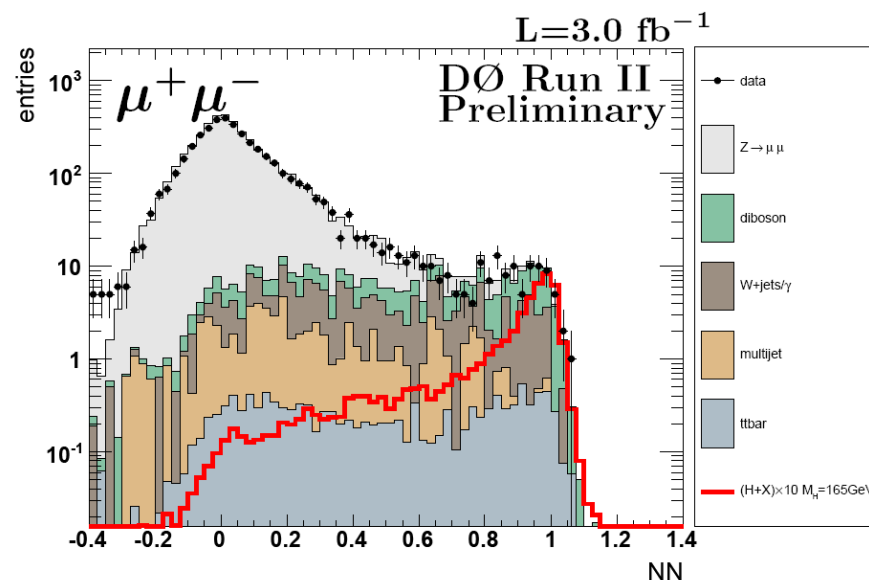

H → W<sup>+</sup>W<sup>-</sup> → l<sup>+</sup>ν l<sup>-</sup>ν (inclusive) (\*)

WH → WWW → l<sup>±</sup>l<sup>±</sup> + X (leptons with same charge)

...

### Example H → WW → llνν

- Search strategy :
- Accumulation of Higgs candidates by dedicated selection cuts (preselection)
  - Require: two leptons with high  $p_T$  and  $E_{T,miss}$
- Final selection by neural network

- Amount of data not yet sufficient

- Combination of CDF and D0 results (all search channels)
- Result from 13.March 2009

What can we expect from TeVatron?

- Combination of all channel allows exclusion at  $m_H=160-170 \text{ GeV}$

- >2011: 95% CL exclusion of the interesting region 115-185 GeV
- Maybe first evidence?

## Important signatures at the LHC:

### ➤ Small masses:

- $gg \rightarrow H \rightarrow \gamma\gamma$
- $gg \rightarrow H \rightarrow ZZ \rightarrow 4l$
- $tt H$  with  $H \rightarrow bb$
- $qq H \rightarrow qq \tau\tau$

### ➤ Large masses:

- $gg \rightarrow H \rightarrow ZZ \rightarrow 4l$
- $gg \rightarrow H \rightarrow WW \rightarrow l\nu l\nu$
- $qqH \rightarrow qq WW$

### ➤ Note: background!

"golden channels":

$H \rightarrow \gamma\gamma$

$H \rightarrow 4l$

➤ signal:

- $\sigma \cdot \text{BR} = 5.7 \text{ fb}$  ( $m_H = 100 \text{ GeV}$ )

➤ background:

- $t\bar{t} \rightarrow WbWb \rightarrow l\nu cl\nu l\nu cl\nu$
- $\sigma \cdot \text{BR} = 1300 \text{ fb}$

➤ selection:

- $P_T(1,2) > 20 \text{ GeV}$
- $P_T(3,4) > 7 \text{ GeV}$
- $M(\text{ll}) \sim M_Z$
- Veto: leptons from B- decays

mass spectrum:

$\Delta M \approx 2$

- Very narrow peak because of excellent measurement of muons.
- **Discovery potential in the region  $m_H$  : 130 GeV to 600 GeV**

**signal:**

$$\sigma^* \text{BR} \sim 50 \text{ fb} \quad \text{BR} \sim 10^{-3}$$

**background:**

➤  $\gamma\gamma$  (**irreducible**): z.B.:

- $\sigma_{\gamma\gamma} \sim 2 \text{ pb} / \text{GeV}$
- $\Gamma_H \sim \text{MeV}$
- needed:  $\sigma(m)/m \sim 1\%$

➤  $\gamma j + j j$  (**reducible**)

- high jet-rejection

➔ Challenge for electromagnetic calorimeters

➤ Discovery potential: 100-140 GeV

**expected signals:**

## Individual and combined significances for 30 fb<sup>-1</sup>

- There are several other search channels
- At the LHC the Higgs boson can be discovered in the full mass region in 30fb<sup>-1</sup>.
- 30fb<sup>-1</sup> corresponds to  $\sim 3$  year of data taking!

$$\text{Sign.} = \frac{N_S}{\sqrt{N_B}}$$

# Remember: Supersymmetrie (SUSY)

- Introduction of a new „SuperSymmetry“ Fermion  $\leftrightarrow$  Boson
- Introduction of SUSY Partners for all SM particles

SM Teilchen (R=1)	SUSY Partner (R=-1)
Quarks $q$	Squarks $\tilde{q}$
Leptons $l$	Sleptons $\tilde{l}$
$W^\pm, Z^0, \gamma,$ Higgs: $h, A^0, H^0, H^\pm$	Neutralinos, $\chi_{1,2,3,4}^0$ Charginos $\chi_{1,2}^\pm$
Gluons $g$	Gluino $\tilde{g}$

## ➔ New contributions to Higgs Mass

- contributions cancel if  $\Delta M < 1 \text{ TeV}$
- ➔ Solution to hierarchy problem

## SUSY can provide explanation for Dark Matter:

If stable, the Lightest Susy Particle leads to the correct relic density in the universe

➔ SUSY is first candidate theory for New Physics  
... and note:  $M_{\text{SUSY}} < 1 \text{ TeV}$

## Example: search for sleptons at LEP

Signatur: 2 acoplanar leptons and missing energy

$\sqrt{s} = 183\text{-}208 \text{ GeV}$  **ADLO**

Sfermions with masses below  $\sqrt{s}_{LEP}/2 \sim 100 \text{ GeV}$  are excluded

### But:

- Many free parameters
- Not yet discovered

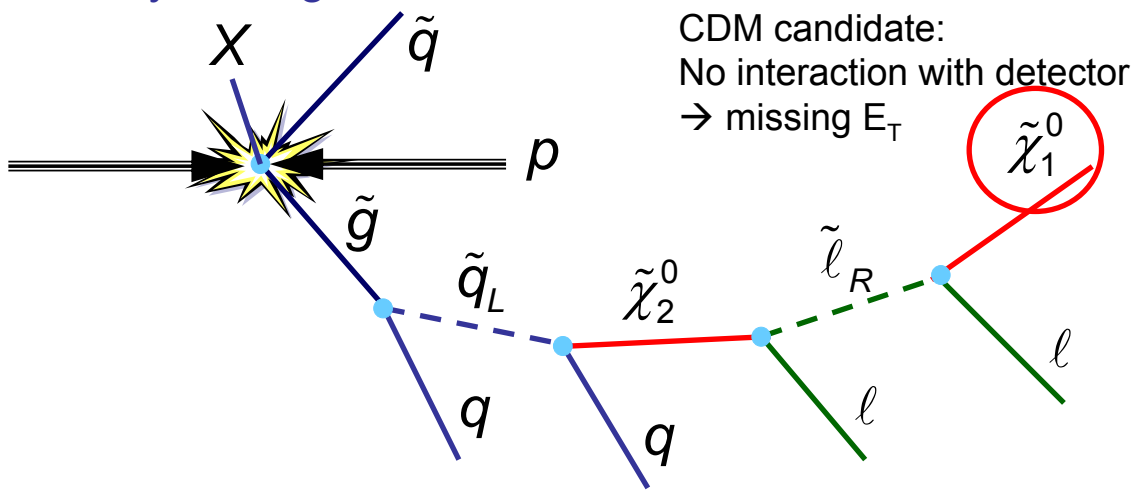

- Searches at all colliders: no signal
- Assumptions: SUSY particles are heavier than the experimentally covered area.

- With its large centre-of-mass energy the LHC is able cover the full interesting region (up to  $m_{\text{squark}} = 3 \text{ TeV}$ )
- At the LHC squarks and gluinos are produced via the strong interaction
  - Cross sections are high

$$gg, q\bar{q}, qq, qg \rightarrow \tilde{g}\tilde{g}, \tilde{q}\tilde{q}, \tilde{q}\tilde{g}$$

- Squark and Gluinos are usually the heaviest SUSY states
- Decay in long cascades to LSP:

- Inclusive selection in order to be independent from exact SUSY model
- In general we expect:
  - Missing  $E_T$
  - Hard jets
  - (Hard leptons)

## ➤ Typical inclusive selection for searches at the LHC:

- $E_{T,miss} > 200$  GeV
- $\geq 4$  Jets with  $p_T > 100, 50, 50, 50$  GeV

## ➤ Good variable to separate signal from background: effective mass

$$M_{\text{eff}} \equiv \sum_i |p_{T(i)}| + E_T^{\text{miss}}$$

- Sum runs over all jets

## ➤ Results are shown for $1 \text{ fb}^{-1}$ only!

## ➤ But note: understanding the detector will take some time; especially for missing $E_T$

## ATLAS simulation:

- Only shown: a particular SUSY model
- In general: very good prospect to discover SUSY if it exists

**5 $\sigma$  discovery reach in mSUGRA plane:**

- With 1 fb<sup>-1</sup>: Squarks with masses up to 1.5 TeV reached.
- Final reach: 3-3.5 TeV
- more difficult at LHC alone: reconstruction of SUSY masses (exclusive decay chains)
- but: needed to provide evidence for a specific SUSY model

**ILC can help in many areas: “LEP for SUSY”**

- inclusive discovery of SUSY “easy” at the LHC
- identification of SUSY model more involved (need ILC)

- Wide range of physics processes covered in pp collisions at the LHC
    - Complete new era in particle physics, unexplored regions.
  - Expect from LHC: Full coverage of the allowed mass range for the **Higgs**
    - Many different channels → solid discovery
    - Golden channels  $H \rightarrow \gamma\gamma$ ,  $H \rightarrow 4l$
    - $5\sigma$  discovery possible with  $30 \text{ fb}^{-1}$  (3 years of data taking)
  - Expect from LHC: Final word on **Supersymmetry**
    - SUSY signal expected below  $\sim 1 \text{ TeV}$  to solve hierarchy problem
    - LHC can cover the region up to  $m_{\text{squark}} \sim 3 \text{ TeV}$
    - First data already enough for discovery in certain scenarios, but: need to understand the detector and the backgrounds first.
  - Final word in many other theories of physics beyond the SM (e.g Leptoquarks)
    - Sensitivity for new particles up to  $\sim 2\text{-}3 \text{ TeV}$  depending on the model
- After  $\sim 20$  years of preparations the first data from the LHC are expected soon
    - Restart operation: fall this year
    - !! Very exciting time for experimentalists and theorists !!
