

# The ALPS Experiment

## *Dark Matter and Particle Physics at Lowest Energies*

A. Lindner, DESY

DESY Summer Student Lecture, 30 July 2010

# Today's Agenda

## > The ALPS Lecture

which is the last one of the common lectures in the past two weeks.

Therefore it might be a good opportunity to ask questions and raise some items.

## > Question Time!

- Nagging issues related to the common lectures.
- Curiosity concerning DESY in general.
- Everything you wanted to know about DESY physics but were afraid to ask (answers **not** guaranteed).
- Other items?

## > “Hands on” with Cosmic Rays and a tour to the ALPS?

# The ALPS Lecture

# The Standard Model of Constituents and Forces

## Constituents:

- > Quarks
- > Leptons

## Forces:

- > electromagnetic
- > strong
- > weak
- > gravitation

<http://www.gridpp.ac.uk/cubes/>

Only the Higgs boson is missing!

LHC is on the way to probe its existence.

# The Standard Model of Constituents and Forces

## Constituents:

- > Quarks
- > Leptons

## Forces:

- > electromagnetic
- > strong
- > weak
- > gravitation

With these few constituents and forces all phenomena observed on earth can be described (in principle).

Since more than 30 years there is not a single particle physics experiment really questioning the Standard Model.

<http://www.gridpp.ac.uk/cubes/>

Only the Higgs boson is missing!

LHC is on the way to probe its existence.

# A Flaw in the Standard Model?

The neutron has a strange property:

It consists of three charged quarks, but does not show any static electric dipole moment.

<http://www.lbl.gov/Science-Articles/Archive/sabl/2006/Oct/3.html>

<http://en.wikipedia.org>

Why do the wave functions of the three quarks *exactly* cancel out any observable static charge distribution in the neutron?

# A Flaw in the Standard Model?

Naively one expects for the neutron electric dipole moment:

$$d_{n\text{-QCD}} \sim 10^{-15} \text{ e}\cdot\text{cm}.$$

$\sim 10^{-15} \text{ cm}$

The data show:  $d_{n\text{-data}} < 10^{-26} \text{ e}\cdot\text{cm}!$

How to explain the difference of at least 11 orders of magnitude?

<http://www.lbl.gov/Science-Articles/Archive/sabl/2006/Oct/3.html>

# Eleven Orders of Magnitude

... expecting a planet and finding the nanoscale ...

# Two Possibilities

- > The vanishing electric dipole moment of the neutron is just accidental. The parameters of QCD are “fine-tuned”, nothing remains to be explained.  
A physicist’s nightmare:

*“I had the dream about meaningful employment  
again last night.”*

- > Can one think of any explanation? If yes, how to confirm this?

# From a Flaw to a new Particle

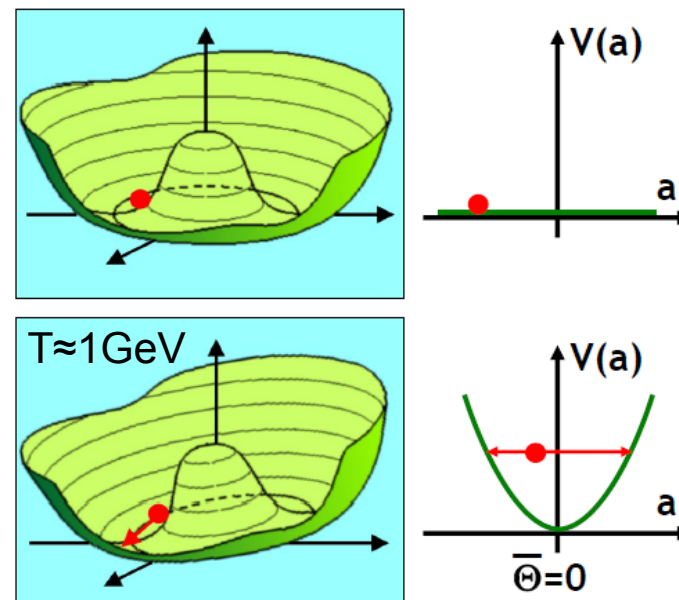

The size of the neutron electric dipole moment is described by a angle  $\Theta$  in QCD. There are no theoretical bounds on  $\Theta$ , but from the missing neutron dipole moment  $\Theta < 10^{-9}$  is concluded.

Is this a “just-so”, a “fine-tuning” of QCD? This would be very unsatisfying.

The theoreticians approach:  
try to find a dynamic explanation!

Peccei-Quinn 1977:

$\Theta$  takes an arbitrary value by spontaneous symmetry breaking at a certain high energy scale  $f_a$  and roles down by non-perturbative QCD effects to its very small value observed in QCD at low energies.

S. Hannestad, presentation at 5th Patras Workshop on Axions, WIMPs and WISPs, 2009

# From a Flaw to a new Particle: the Axion

Wilczek and Weinberg independently noticed 1978:

The oscillations of  $\Theta$  constitute an **axion**-field (christened by Wilczek).

## Summary:

One can explain the vanishing electric dipole moment of the neutron in QCD if a new particle, the axion, exists.

The axion “cleans” QCD.

**ἄξιον = worthy, deserving**

# Properties of the QCD Axion

- > The axion behaves like a light cousin of the  $\pi^0$ . It couples to two photons.
- > Mass and the symmetry breaking scale  $f_a$  are related:  
$$m_a = 0.6\text{eV} \cdot (10^7\text{GeV} / f_a)$$
- > The coupling strength to photons is  
$$g_{a\gamma\gamma} = \alpha \cdot g_\gamma / (\pi \cdot f_a),$$
 where  $g_\gamma$  is model dependent and  $O(1)$ .

- > The axion abundance in the universe is  
$$\Omega_a / \Omega_c \sim (f_a / 10^{12}\text{GeV})^{7/6}.$$

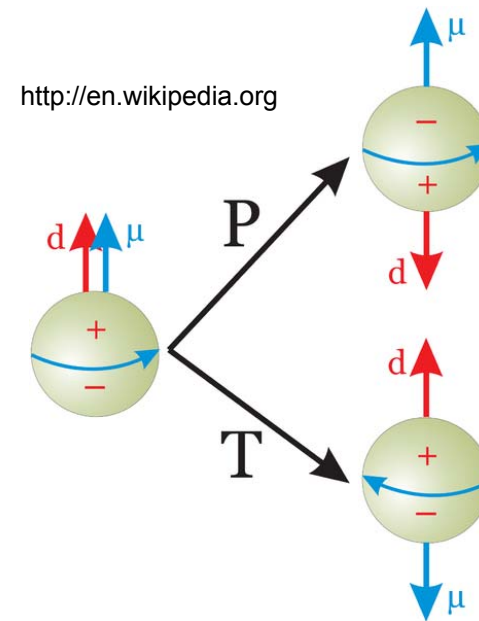

# A Flaw and fundamental Properties of Nature

Electric and magnetic dipole moments of the neutron are related to fundamental symmetries:

- > P (parity), T (time reversal) and C (charge conjugation) .

Neutron                  Antineutron          Antineutron

If the neutron has an **electric dipole moment** in addition to the measured **magnetic dipole moment**, C·P is not conserved. Both moments would change from parallelism to anti-parallelism.

The strong interaction conserves CP ↔ no neutron electric dipole moment

# Detour: C-P is not only an academic Question!

C-P violation is essential to explain

why matter and antimatter did not annihilate completely about  $10^{-34}$ s after the Big Bang

and hence essential to explain

our existence!

Unfortunately:

- > C-P violation in weak interaction is much too weak for an explanation.
- > QCD could do the job, but experiments show that QCD conserves C-P!  
This is understandable, if the axion exists.

We still don't know, why we are here.

# Detour: C-P is not only an academic Question!

C-P violation is essential to explain

why in the very early universe the ratio of matter to antimatter was

$$\text{Matter/Antimatter} = 1+10^{-9}$$

one additional grain of sand!

<http://www.weltmaschine.de>

We and all what we see are made from this  $10^{-9}$  fraction.

# Table of Contents

- > An Introduction to the Axion

- > The ALPS Experiment at DESY
- > Outlook on possible future Activities
- > Summary

# The Standard Model beyond Earth

The great success on earth:

With these few constituents and forces all phenomena observed on earth can be described (in principle).

Since more than 30 years there is not a single particle physics experiment really questioning the Standard Model.

is questioned by astrophysics and cosmology:

**The Standard Model (without axions!) describes only 4% of the matter-energy content of the universe!**

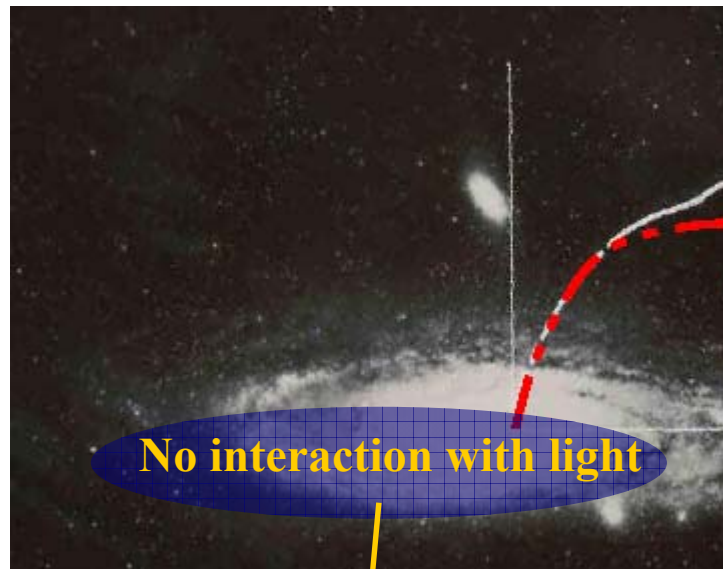

# Observational Evidence for Dark Matter (1)

Rotation of galactic disks:

Dark Matter and experiments:

<http://cdms.berkeley.edu/experiment.html>

Dark Matter  $\approx 10 \cdot$  Luminous Matter

## Observational Evidence for Dark Matter (2)

Motions of galaxies in clusters:

Clusters do not diffuse in spite of high speed of galaxies.

(Dark component first proposed 1933 by F. Zwicky after analysis of the Coma cluster)

Dark Matter  $\approx 30 \cdot$  Luminous Matter

## Observational Evidence for Dark Matter (2)

Motions of galaxies in clusters:

Clusters do not diffuse in spite of high speed of galaxies.

(Dark component first proposed 1933 by F. Zwicky after analysis of the Coma cluster)

Dark Matter  $\approx 30 \cdot$  Luminous Matter

## Observational Evidence for Dark Matter (3)

Hot gas in galaxy clusters:

Hot gas (measured by X-ray emission due to  $e^-$  bremsstrahlung) contains too much kinetic energy to be bound by luminous matter in the cluster.

Mass (hot gas)  $\approx$   
 $5 \cdot$  Luminous Matter

Dark Matter  $\approx 30 \cdot$  Luminous Matter

# How to find Dark Matter in the Universe?

Search for Dark Matter via gravitational effects  
(kind of definition of “dark”):

- > bound systems  
(galaxies, clusters of galaxies, hot gas as shown before)
- > distortion of images due to gravitational force on light  
“gravitational lensing”

# Gravitation distorts Images

<http://astronomyonline.org/Cosmology/GravitationalLensing.asp>

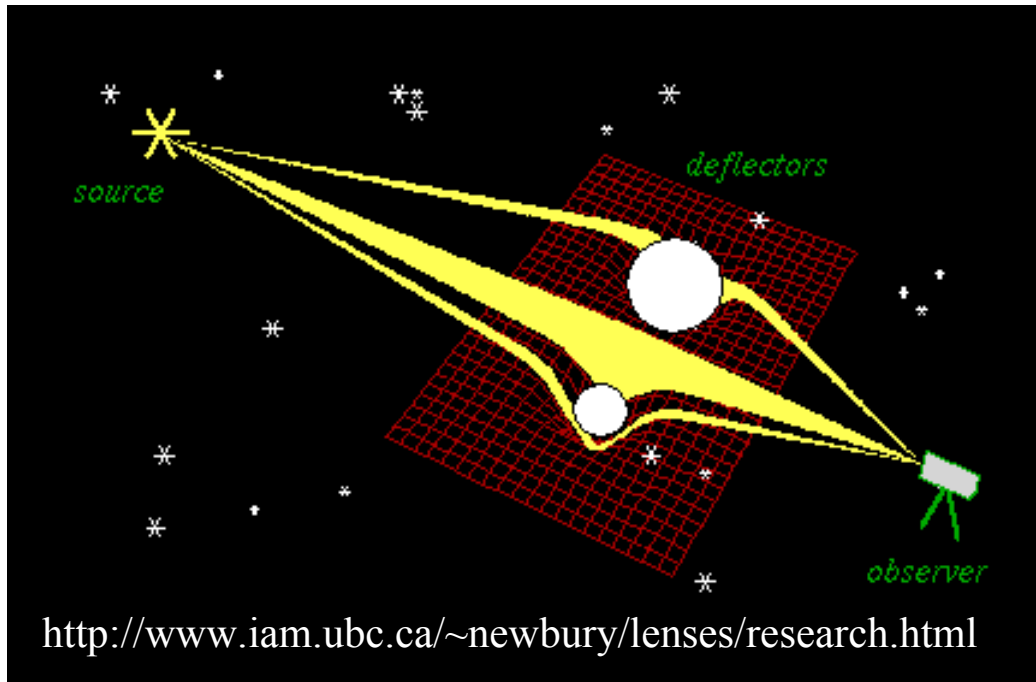

# Gravitation distorts Images

<http://astronomyonline.org/Cosmology/GravitationalLensing.asp>

# Gravitation distorts Images

Gravitational lensing:  
Derive mass of "lens" from  
properties of image .

# Observational Evidence for Dark Matter (4)

Dark Matter  $\approx 30 \cdot$  Luminous Matter

# The Smoking Gun Observation (?)

## Bullet cluster 1E 0657-56: merging of two galaxy clusters

(Clowe et al., astro-ph/0608407v1)

Contours from gravitational lensing

hot gas from X-rays

# The Smoking Gun Observation (?)

Bullet cluster 1E 0657-56

hot gas (X-ray)

from gravitational lensing

# The Smoking Gun Observation (?)

# Further Evidences for Dark Matter

- > Cosmic Microwave Background Radiation (CMBR) analyses

- > Structure formation in the universe
  - non relativistic “cold” dark matter is required as seeds for galaxies!

## Model: Galaxies “swim” in a Halo of Dark Matter

However, the detailed structure of such a halo is a matter of intense discussion!

# More dark Stuff: Dark Energy drives the Universe apart

Measurements of Supernovae Ia by the Hubble Space Telescope (and others):

- > There is a repulsive force ("anti-gravitation") best explained by "dark energy" (Einstein's  $\Lambda$ )
- > Dark energy is an attribute of space. Dark energy per volume is constant. The larger the universe, the larger the fraction of dark energy!
- > The universe expands currently with increasing speed!
- > This scenario is strongly confirmed by analyses of the Cosmic Microwave Background Radiation and many other data!

# Precision Cosmology!

<http://lambda.gsfc.nasa.gov/>

- > Geometry of the Universe: flat
- > Age of the Universe:  $13.69 \pm 0.13$  Gyr
- > Hubble Constant:  $72 \pm 3$  km s<sup>-1</sup> Mpc<sup>-1</sup>
- > Fluctuations compatible with inflation
  
- >  $\Omega_b$  (baryons):  $0.044 \pm 0.003$
- >  $\Omega_c$  (dark matter):  $0.214 \pm 0.027$
- >  $\Omega_\Lambda$  (dark energy):  $0.742 \pm 0.030$
- > Early star light (reionisation):  $\Omega_v \ll \Omega_{dm}$

In very good agreement to all other data (supernova search with HST, galaxy counting, Big Bang Nucleon-synthesis, ...)

# Why LHC alone is insufficient to understand the Cosmos

- > LHC probes the very early universe when it was very small, hot and dense.
- > Dark energy was totally negligible at those times.
- > Surprisingly, we understand the early universe from fractions of a second to minute scales better than today's universe.
- > Dedicated "low energy" experiments are required to get a clue on Dark Energy.

# Dark Matter and Dark Energy in this Room

Why did physics overlook  
Dark Matter and Dark Energy so long?

Densities in this room:

- Matter (earth's crust):  $3 \text{ g/cm}^3$
- Dark Matter (DM):  $0.00000000000000000000000005 \text{ g/cm}^3$
- Dark Energy (DE):  $0.000000000000000000000000000001 \text{ g/cm}^3$

Why dominates matter here and DM und DE in the Universe?

- Matter is “clumpy“, interacts strongly: planets are formed.
- Dark Matter interacts only very weakly: halos around galaxies.
- Dark Energy is distributed uniformly all over the universe.

# Hitchhiker's Guide to the Galaxy

*There is a theory which states that if ever anybody discovers exactly what the Universe is for and why it is here, it will instantly disappear and be replaced by something even more bizarre and inexplicable.*

*There is another theory which states that this has already happened.*

**Douglas Adams**

*English humorist & science fiction novelist (1952 – 2001)*

# Some Caveats on our Picture of a strange Universe

> The Copernican principle is used to interpret the data.

- The Universe in our neighborhood is not special.

Homogeneity (similarity in all regions of space)

Isotropy (similarity in all directions).

This principle is

- compatible with observations (if you accept “Dark Energy”!),

- but fundamentally untested!

> Which is the relevant scale for homogeneity of the Universe?

Does one have to take into account in-homogeneities when calculating cosmological parameters?

> Do we really understand gravity in the weak acceleration regime?

- Pioneer anomaly: Slava G. Turyshev and Viktor T. Toth, arXiv:1001.3686v1 [gr-qc]
- Swing-by anomaly: J.D. Anderson et al., PRL 100, 091102 (2008)

For the time being ...

... let's stick to the general accepted paradigm ...

**"Shhhh. That's the theoretical physicists' new particle uniform.  
If you can't see it, you won't be allowed to graduate."**

... and search for dark matter and dark energy.

# Properties of the Dark Matter

- > Dark Matter  $\approx 30 \cdot$  luminous matter (stars)
  - Dark baryons (p, n)  $\approx 5 \cdot$  luminous matter  
(indirect observations (gas), big bang nucleosynthesis, CMBR)
  - Unknown "dark" particles  $\approx 6 \cdot$  baryonic matter
    - Only gravitational (and weak) interaction
    - Should be non-relativistic ("cold")

These "dark" particles are not members of the Standard Model!

# The prime DM Candidates

## 1. Weakly Interacting Massive Particles: WIMPs

Most promising candidate: lightest supersymmetric particle (neutralino, a linear combination of photino, zino and higgsinos, to be found at LHC?),  
very heavy (around  $10^{11}\text{eV}$ ).

## 2. Axion or Axion Like Particles: ALPs

Invented to explain CP conservation in QCD (“why is the electric dipole moment of the neutron zero or extremely small?”).  
Non-thermal production in the early universe,  
very light (around  $10^{-5}\text{eV}$ ).

# Dark Matter could be Axions!

Due to their non-thermal production in the universe light axions would constitute *cold* dark matter.

Such axions couple extremely weakly to matter: the “invisible” axion.

**The axion was *not* invented to solve the Dark Matter problem!**

H. Baer, presentation at 5th Patras Workshop on Axions, WIMPs and WISPs, 2009

# ... and here we are:

Figure 1: Exclusion ranges as described in the text. The dark intervals are the approximate CAST and ADMX search ranges. Limits on coupling strengths are translated into limits on  $m_A$  and  $f_A$  using  $z = 0.56$  and the KSVZ values for the coupling strengths. The “Laboratory” bar is a rough representation of the exclusion range for standard or variant axions. The “GC stars and white-dwarf cooling” range uses the DFSZ model with an axion-electron coupling corresponding to  $\cos^2 \beta = 1/2$ . The Cold Dark Matter exclusion range is particularly uncertain. We show the benchmark case from the misalignment mechanism.

- > There could be a new particle, the axion, at the meV scale.
  - $m_a \approx 1 \text{ meV}$
  - $f_a \approx 10^{10} \text{ GeV}$
  - $g_{a\gamma\gamma} \approx 10^{-13} \text{ GeV}^{-1}$
- > If found, it might give insight into physics at very large energy scales ( $f_a$ ).
- > However, it would interact extremely weakly with the Standard Model constituents.
- > Such an axion could make up most of the mass of the Universe.

# Table of Contents

- > An Introduction to the Axion
- > Dark Stuff in the Universe
- > From Axions to ALPs and WISPs
- > How to search for WISPs
- > The ALPS Experiment at DESY
- > Outlook on possible future Activities

# From Axions to ALPs and WISPs

There might be much more than a QCD axion:

> **ALPs**: “axion-like particles”

String Axiverse

A. Arvanitaki, S. Dimopoulos, S. Dubovsky, N. Kaloper, and J. March-Russell,  
arXiv:0905.4720 [hep-th]

*String theory suggests the simultaneous presence of many ultralight axions, possibly populating each decade of mass down to the Hubble scale  $10^{-33}$ eV. Conversely the presence of such a plenitude of axions (an “axiverse”) would be evidence for string theory, ...*

> **WISPs**, **W**eakly **I**nteracting **S**lim **P**articles,  
(axions and ALPs, hidden sector photons, mini-charged particles) occur naturally in string-theory motivated extensions of the Standard Model

Naturally Light Hidden Photons in LARGE Volume String Compactifications

M. Goodsell, J. Jaeckel, J. Redondo and A. Ringwald,  
arXiv:0909.0515 [hep-ph], JHEP 0911:027,2009

*Extra “hidden”  $U(1)$  gauge factors are a generic feature of string theory that is of particular phenomenological interest. They can kinetically mix with the Standard Model photon and are thereby accessible to a wide variety of astrophysical and cosmological observations and laboratory experiments.*

# WISPs: Illuminating Hidden Worlds?

– Light hidden  $U(1)$ s ... –

9

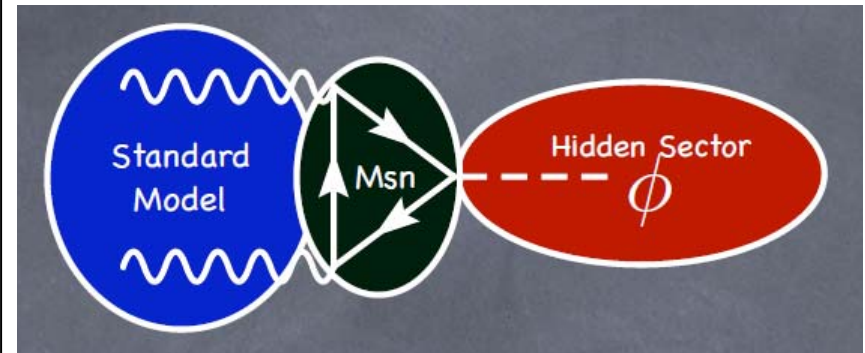

- Embeddings of the standard model in string compactifications often contain even several hidden sector  $U(1)$  gauge factors (cf. consistency conditions, e.g. tadpole/anomaly cancellation), e.g.

– in type II string theory with branes:

A. Ringwald (DESY)

SLAC, September 2009

- > Very massive messengers may communicate between “our” Standard Model world and hidden sectors of a stringy universe.

In this sense WISP searches try to illuminate hidden worlds and probe very high energy scales.

# Summary on Motivation

- > The axion remains interesting as a
  - solution to the CP conservation of QCD,
  - candidate for Dark Matter.
  
- > There might be a plenitude of **Weakly Interacting Slim Particles**
  - occurring naturally in string-theory inspired extensions of the Standard Model,
  - opening a window to physics beyond the TeV scale.
  
- > Theory starts to develop detailed scenarios and predictions for WISPs to be probed by experiments.
  - Not only detections, but also upper-limits on WISP productions might become important ingredients for theory.

# An Experimentalist's Motivation: Just Coincidences?

- > Neutrinos have masses at the **meV scale**.
- > The density of Dark Energy in our Universe is  $10^{-29}\text{g/cm}^3$ , being equivalent to  $\rho_{\text{DE}} \cong (2 \text{ meV})^4$ .

The cosmological constant problem,  
*S. Weinberg*,  
Rev. Mod. Phys.  
61, 1–23 (1989)

ute to the effective cosmological constant. In order to keep  $\rho_V < 10^{-48} \text{ GeV}^4$ , we need the scalar field adjustment to cancel the effect of gravitational and electromagnetic field fluctuations down to frequencies  $10^{-12} \text{ GeV}$ ; for this purpose we must have  $m_\phi < 10^{-12} \text{ GeV}$ . A field this light will have a macroscopic range:  $\hbar/m_\phi c \gtrsim 0.01 \text{ cm}$ .

- > Today's energy density of the universe is about **(meV)<sup>4</sup>**.

Does this hint at new physics at the meV scale?

Presumably, LHC & Co. results will not explain these phenomena.

**Let's strive for dedicated experiments!**

Note:  
 $P_{\gamma \rightarrow \Phi \rightarrow \gamma} \sim g^4$

G. Ruoso et al.  
(BFRT Experiment),  
*Z. Phys. C* 56 (1992) 505

# Axion Production in a magnetic Field

- > The production (and re-conversion) of WISPs takes place in a coherent fashion.

For ALPs ( $\Phi$ ):

$$P_{\gamma \rightarrow \phi}(B, \ell, q) = \frac{1}{4} (g B \ell)^2 F(q\ell) \quad F(q\ell) = \left[ \frac{\sin\left(\frac{1}{2}q\ell\right)}{\frac{1}{2}q\ell} \right]^2 \quad \begin{array}{l} q = p_\gamma - p_\phi \\ \ell: \text{length of } B \text{ field} \end{array}$$

With  $P_{\gamma \rightarrow \phi} = P_{\phi \rightarrow \gamma} = P$ :  $g = (P)^{1/4} \cdot 2 \cdot / (\ell \cdot B) / F^{1/2}$

# A powerful Laser System for ALPS

> Brute force:  
a very powerful laser

> example:  
laser for welding

D. Tanner, PATRAS 2009

> Problems

- significant energy deposition inside the HERA dipole (superconducting) is to be avoided.
- laser properties not suited to guide the beam through the bent tube of the dipole.

# A powerful Laser System for ALPS

- > Trick:  
the light of a relatively low power laser with excellent beam characteristics is reflected back and forth inside the magnet, the light is stored inside an optical resonator (cavity) thus enhancing the effective laser power.

# A powerful Laser System for ALPS

- > Trick:  
the light of a relatively low power laser with excellent beam characteristics is reflected back and forth inside the magnet, the light is stored inside an optical resonator (cavity) thus enhancing the effective laser power.

# A powerful Laser System for ALPS

## > Challenges:

- The distance of the mirrors and the wavelength have to match within  $\approx 10$  nm in spite of acoustic noise and other fluctuations. This is guaranteed by an electronic feedback loop adapting the laser light wavelength to the mirror distance
- The mirrors have to reflect the light back and forth on exactly the same path.
- This is to be done without access to the mirror in the middle of the magnet. There is no way to firmly fix this mirror!

- > ALPS succeeded to realize such a set-up for the first time ([doi:10.1016/j.nima.2009.10.102](https://doi.org/10.1016/j.nima.2009.10.102))

*Resonator  
detuned.*

*tuned,  
but not "locked".*

*Locked!*

# The ALPS Lasers

> Result of laser upgrades for data taking August to December 2009:

The 1300 W laser power is achieved from 4.4 W built-up in the resonator by a factor of 300.

The power is limited by the lifetime of the mirrors in vacuum (10-30 h) due to heating. However, a significant further improvement would also require investments into beam stabilization and new locking electronics.

1300 W is much more than we ever dreamt of!

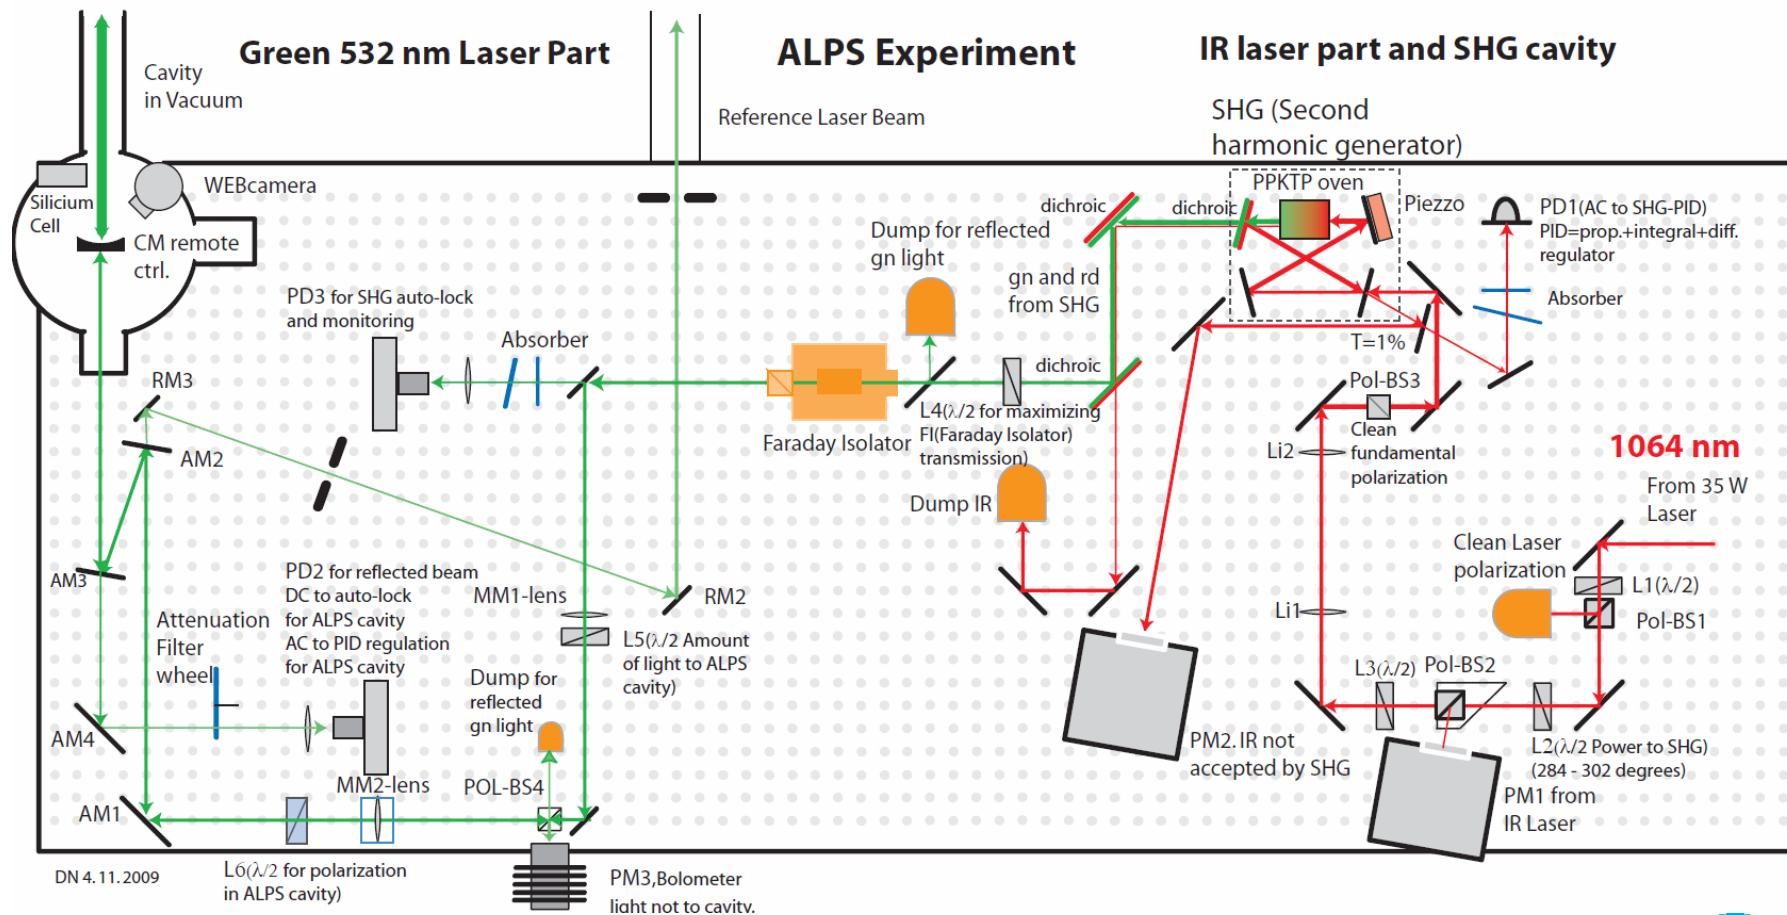

# The ALPS Laser System

> We are running a quite complex and delicate apparatus!

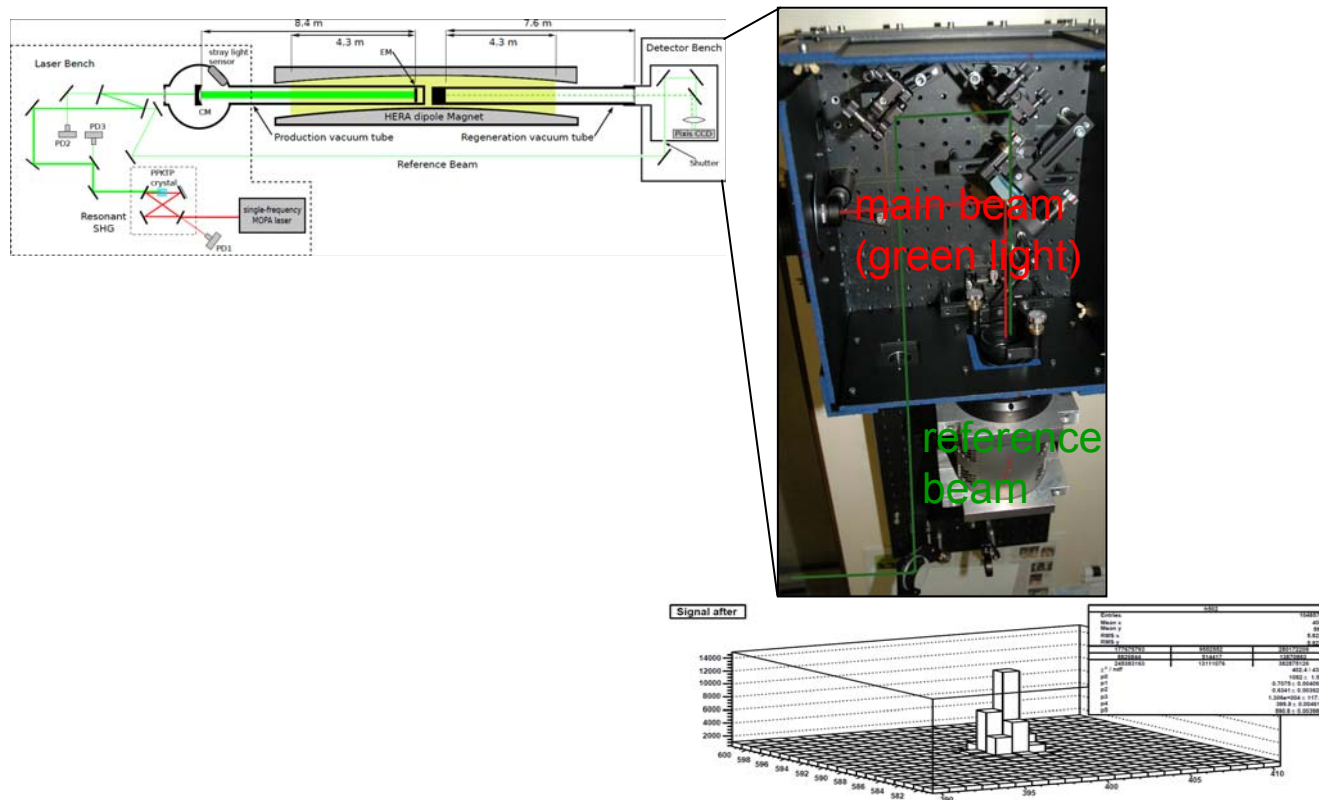

# The ALPS Laser System

> We are running a quite complex and delicate apparatus!

# The ALPS Detector

- > Conventional low noise CCD, where the light is focused onto very few pixels to minimize dark current and read-out noise.

Beam spot on the CCD  
(pixel size 13  $\mu\text{m}$ ).

# ALPS at Work

Steps of data taking:

1. Test alignment with open detector tube and fraction of laser light passing the mirror ( $10^{-4}$ ).
2. Demount detector and detector tube.
3. Close tube and reinstall everything.
4. Take data (1h CCD exposures).

# ALPS at Work

Steps of data taking:

5. Demount detector and detector tube.
6. Open the tube and reinstall everything.
7. Test alignment with open detector tube and fraction of laser light passing the mirror ( $10^{-4}$ ) to confirm that the alignment has not changed.

# A Glimpse into the Data Analysis

- > Each 1 h exposure results in one entry (ADU value of the signal pixel) into the histogram:

pixel (147,165)

Compare mean ADU for  
“Laser on” and “Dark frames”.

# A Glimpse into the Data Analysis

- > Test the CCD and the data analysis with a photon beam of extremely low intensity: between 5 mHz and 50 mHz.

pixel (147,165)

From Gaussians fitted to the data:

$\Delta$ mean	$\Delta$ width
$23.27 \pm 3.20$	$-5.86 \pm 3.20$

pixel (147,165)

A photon flux of  $(7.9 \pm 1.2)$  mHz ( $3 \cdot 10^{-21}$  W) is detected which agrees nicely to the expectation.

# A Glimpse into the Data Analysis

> Example for a data run:

From Gaussians fitted to the data:

$\Delta$ mean	$\Delta$ width
$-0.24 \pm 3.54$	$0.96 \pm 2.50$

In none of the preliminary data analyses any evidence for WISP production shows up.

# ALPS Results: <http://arxiv.org/abs/1004.1313>

- > ALPS is the most sensitive experiment for WISP searches in the laboratory. For axion-like particles, ALPS probes physics at the “multi-10-TeV scale”!

← pseudoscalar and scalar →  
axion-like particles

← hidden sector photons and minicharged particles →

← Filling a gap remaining from astrophysics and other experiments! →

PLB 689 (2010), 149

# ALPS Summary

- > Experience gathered with ALPS is a firm foundation for continuing to probe the hints for WISPs, now on larger scales.
- > The essential strength of ALPS is the collaboration of particle physicists (theory and experiment) and laser physicists from the gravitational wave detector community.
- > Infrastructure and large magnets provided by a lab like DESY are essential to accomplish experiments like ALPS.
- > Significant efforts required to compete with astrophysics!

compiled by J. Jäckel and A. Ringwald

# Hints for ALP Physics: Cosmological TeV $\gamma$ Propagation

TeV photons should be absorbed by  $e^+e^-$  pair production due to interaction with the extragalactic background light (EBL):

$$\gamma_{\text{TeV}} + \gamma_{\text{eV}} \rightarrow e^+ + e^-$$

However, the TeV spectra of distant galaxies do hardly show any absorption.

M. Roncadelli, presentation at the 4th Patras Workshop on Axions, WIMPs and WISPs, 2008

TeV photons may “hide” as ALPs!

# A possible Scenario for ALPS II

> Still a way to go!

# More Beam Time for Lab Experiments?

**CAST:** expected ALPs flux from the sun for  $g=10^{-10} \text{ GeV}^{-1}$ :  
 $\Phi_a = g^2_{10} \cdot 3.75 \cdot 10^{11} \text{ 1/cm}^2/\text{s} = 1.5 \cdot 10^{12} \text{ s}^{-1}$

**ALPS:** expected ALPs flux for  $g=10^{-10} \text{ GeV}^{-1}$ :  $\Phi_a = 3 \cdot 10^3 \text{ s}^{-1}$

Nine orders of magnitude are difficult to beat just by beam time:  
*(the ALPs have to convert into photons for detection:  $\sim g^4$ )*

Need a more clever approach!

# Prospects for ALPS-II Components

- > Laser with optical cavity to recycle laser power, switch from 532 nm to 1064 nm.
- > Magnet: upgrade to 2+2 or even 6+6 (?) HERA dipoles instead of  $\frac{1}{2}+\frac{1}{2}$  (260 Tm on each side equivalent to 2 LHC dipoles).
- > Regeneration Cavity and single photon counter (transition edge sensor?).

All set up in a clean environment!

# ALPS @ DESY in Hamburg

# A possible Scenario for ALPS II

## Basics:

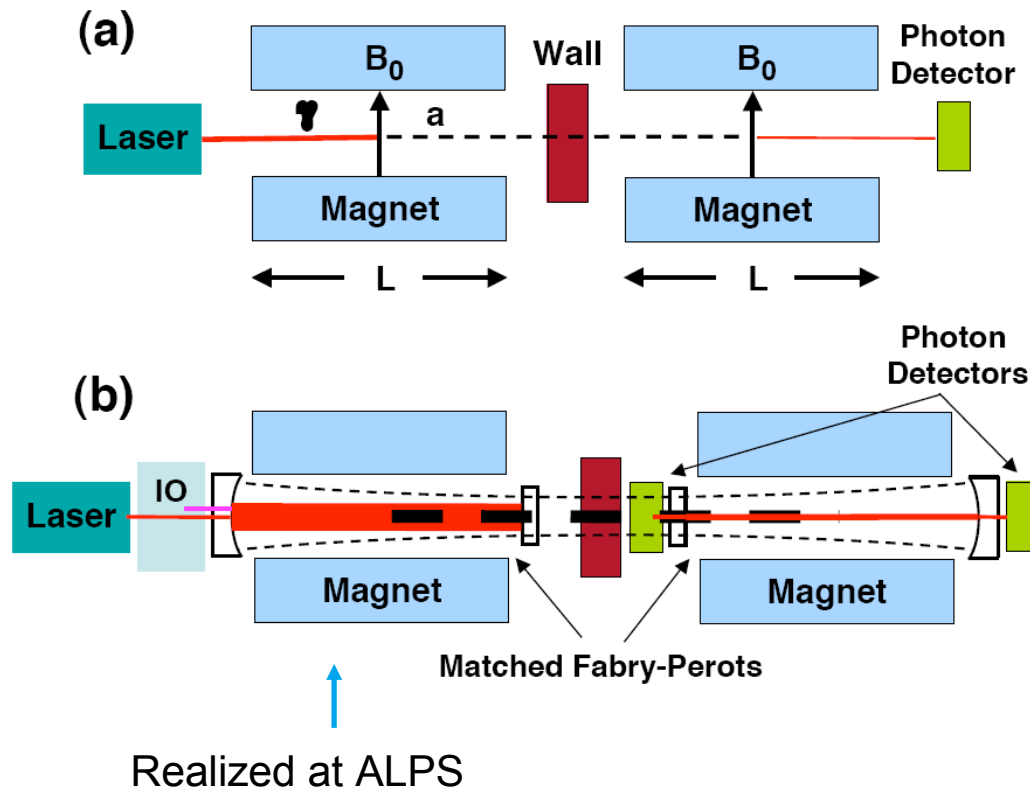

- > Need to switch to a scenario with at least two magnets in order to have a handle on both mirrors defining the resonator.  
At ALPS there is no access and no firm support of the mirror in the middle of the HERA dipole.
- > Ensure clean room conditions from the beginning.  
At ALPS this was introduced at a late stage.

# A possible Scenario for ALPS II

Essential:

- > Implementation of a second cavity in the regeneration part of the experiment to enhance the conversion probability  $\text{WISP} \rightarrow \text{photon}$ .

“Resonantly enhanced Axion-Photon Regeneration”

The article text discusses the search for WISPs and the ALPS experiment.

**Physics: Not a WISP of evidence**

Nature 465, 271 (20 May 2010) | doi:10.1038/465271c  
Published online 19 May 2010

Cited research: *Phys. Lett. B* doi:10.1016/j.physletb.2010.04.066 (2010)

In extensions to the standard model, which describes the fundamental particles and forces of physics, some theorists have proposed the existence of very light subatomic particles called WISPs. These could be dark matter, which keeps a spinning galaxy from flying apart.

One way to detect WISPs would be to look for the rare conversion of light particles to WISPs, and later back to photons. In between these conversions, a WISP could zip through any barrier. So Axel Lindner at DESY, the German electron synchrotron in Hamburg, and his colleagues shone green laser light at a 'wall', a thick piece of light-absorbing material, hoping that a few photons might pop out the other side. They increased the chances of a WISP conversion by using optical resonators to boost the power of the laser light and by applying a strong magnetic field. But the researchers did not detect any emerging photons, limiting the chance of a WISP conversion to nearly  $1$  in  $10^{25}$  — the most sensitive limit yet. **E.H.**

# Summary

- > There are some fascinating leftovers from main stream particle physics
  - WISP physics, GeV dark forceswhich may hide solutions to long-standing and fundamental physics question
  - CP conservation in QCD, dark matter, (dark energy), astrophysics miracles
- > Efforts to explore the leftovers are very moderate.

> **We should close these gaps of knowledge!**

# Thanks to the ALPS Collaboration!
