Pre-existing betatron motion and spin flipping with RF fields in storage rings

Desmond Barber

Deutsches Elektronen-Synchrotron, DESY, Hamburg, Germany
University of Liverpool, UK
Cockcroft Institute, Daresbury, UK

30 September 2010
For students of the recent history of these matters:

Every cloud has a silver lining.

– English proverb
Physics now stands on three legs – has three branches

- Experimental physics
- Theoretical physics
- Computational physics

– FZ Juelich: publicity material about the powerful computers.
Essential, pre-requisite tools and knowledge:

- The **T-BMT equation** for spin motion:
  \[
  \frac{d\vec{S}}{ds} = \vec{\Omega}(z,s) \times \vec{S}; \quad \vec{\Omega}(z,s) = \vec{\Omega}_0(s) + \vec{\omega}(z,s); \quad z = (x, p_x, y, p_y, \sigma, \delta); \quad \theta = 2\pi s/C
  \]

- The 1-turn periodic coordinate system on the CO: \( \hat{l}(s), \hat{n}_0(s), \hat{m}(s) \)

- The **invariant spin field** (ISF):
  \[ \hat{n}(z,s) \quad \text{or} \quad \hat{n}(z,\theta); \quad \hat{n}(z,s+C) = \hat{n}(z,s) \]

- The **spin tune** on the closed orbit \( \nu_0: = a\gamma_0 \) in a simple perfectly flat ring.

- The **uniform invariant frame field** (u-IFF): \( \hat{u}_1(z,s), \hat{n}(z,s), \hat{u}_2(z,s) \)

- The **equivalence class of amplitude dependent spin tunes** (ADST).

- The **naive single resonance model** (SRM) for the ISF and ADST: a single Fourier harmonic of \( \vec{\omega}(z,s) \cdot (\hat{l}(s) - i\hat{m}(s)) \) has dominant control of spin motion

  \[ \Rightarrow \text{the spin tune } \nu_0 \text{ on the closed orbit matches an orbital tune: } \nu_0 = \kappa = k_0 \pm Q_1, \ k_0 \pm Q_{II}, \ k_0 \pm Q_{III} \text{ or } \nu_0 = \kappa = k_0 \pm Q_{rf} \text{ for an integer } k_0. \]

- The well known notation for the SRM. For example:
  \[ \delta = \nu_0 - \kappa, \quad \text{the resonance strength } \epsilon_{\kappa} \]

- The **naive Froissart–Stora formula** for survival of vertical polarisation \((1960!)\) when \( \delta \) crosses 0:

  \[
  \frac{S_{y,\text{final}}}{|S|} = 2 \exp(-\Xi) - 1 = 2 \exp\left(-\frac{\pi|\epsilon_{\kappa}|^2}{2\alpha_{FS}}\right) - 1, \quad \alpha_{FS} = \frac{d\delta}{d\theta}
  \]
The SLIM/SLICK formalism

Linearised orbital and spin motion for first order analytical estimates of radiative depolarisation in electron storage rings, e.g., HERA, eRHIC, ELIC, ENC@FAIR, SuperB, LHeC.....

Attach an orthonormal 1-turn periodic coordinate system \( \hat{l}(s), \hat{n}_0(s), \hat{m}(s) \) to the closed orbit. 
\( \hat{n}_0(s) \) obeys the BMT equation on the closed orbit – “the stable spin direction”.

\[
\vec{S} \approx \hat{n}_0(s) + \alpha \hat{m}(s) + \beta \hat{l}(s)
\]

\( \alpha, \beta \): 2 small spin tilt angles — have subtracted out the big rotations!

\[
\hat{M}_{8 \times 8} = \begin{pmatrix}
    M_{6 \times 6} & 0_{6 \times 2} \\
    G_{2 \times 6} & D_{2 \times 2}
\end{pmatrix}
\]

acting on \( \vec{\varepsilon} = (x, p_x, y, p_y, \sigma, \delta) \) and \( \alpha, \beta \)

\( G_{2 \times 6} \) represents the linearised solution of the T-BMT equation for \( \alpha, \beta \).

This is the **SLIM formalism**: originally A.W. Chao 1981 – working at DESY.

Theory and codes developed further by H. Mais and G. Ripken, D. Barber.

D. Barber: also a thick-lens version, SLICK and with Monte-Carlo extensions, SLICKTRACK.
Also: acceleration and spin flip

Using $G_{2\times 6}$ to get $\epsilon^{\text{tot}}, \epsilon^{\text{rfd}}$ etc

See for example:

Just need the 1-turn $G_{2\times 6}$ for free synchro-betatron motion and with the RFD, a trivial extension for the forced motion + a term for the RFD itself.

For example, for free synchro-betatron motion:

$$\tilde{\epsilon}_k^{\text{sb}} = \frac{1}{2\pi} (1 - i) \bar{G}(C,0) \sqrt{2J_k e^{-i \phi_k}} \bar{\tilde{v}}_k(0)$$

Or do long term tracking and averaging to get the Fourier integral.

Any ring geometry, any misalignment, any linear coupling.
Full 6-D orbital motion!
No need for obscene contortions!
Getting $\epsilon$ by tracking or eigenanalysis: including the (inhomogeneous) rf dipole with the matrix $G_{2\times 6}$

The structure of EpsSLICK

- Read optic/layout and control files
- Choose misalignments
- Correct the C.O. “in line” 6x6 formalism
- Final C.O.
- Linear, uncoupled optics checks

Spin flip simulations
Inv. spin field Inv. tensor field by stroboscopic averaging (Full sync–beta motion)
(Full 3–D spin motion)

8x8 linearised spin–orbit tracking with 2x6 ‘G’ matrix + RFD $\rightarrow \epsilon_{\text{ref}}, \epsilon_{\text{rot}}, \epsilon_{\text{various parts}}$
Any coupling
Any misalignment

8x8 linearised eigen–analysis with 2x6 ‘G’ matrix + RFD $\rightarrow \epsilon_{\text{ref}}, \epsilon_{\text{int}}, \epsilon_{\text{various parts}}$
Any coupling
Any misalignment

= old (SLICK) = New = Old + New
Diagnostics!

Switch spin-orbit coupling off/on to see what does what.

For example:
Check that $\epsilon^{\text{rfd}}$ comes out correctly.
Study contributions from $y''$, $y'$, $y$.
Getting the relative signs right.
The scaling factors $E = \varepsilon / \varepsilon_{rd}$ of the resonance strength in COSY for protons at 2.1 GeV/c

The values for $E_{y'' \gamma'(rfd+ring)}$ confirm earlier preliminary results (2006!) from A. Lehrach.

The values for $E_{y'' \gamma'}(rfd + ring)$ are confirmed by M. Vogt with the code SPRINT.

Nothing unexpected – just well known effects. Subject closed.
Spin flip simulations:

Extend the 8x8 formalism of basic SLICK to handle full 3-D spin motion. A perfect formalism for such problems.

\[ \pm 4 \text{ kHz} \equiv \pm 57|\epsilon_r f| \text{.} \] Spins initially parallel to ISF,…i.e vertical.
Run down the RF amplitude at the end. \( \Xi = 1 \implies S_{n_0}^{\text{final}} = -0.264. \)
Now look properly

beyond the naive SRM:

\[
\hat{n}_{\text{RF}}(\phi_{\text{RF}}) = (\text{sgn} \, \delta_{\text{RF}}) \frac{\left( \delta_{\text{RF}} \hat{n}_0(s) + |\epsilon_{\kappa}^\text{RF}| (\hat{l}(s) \cos \phi_{\text{RF}} + \hat{m}(s) \sin \phi_{\text{RF}}) \right)}{\Lambda_{\text{RF}}},
\]

where \( \delta_{\text{RF}} = \nu_0 - \kappa_{\text{RF}} \), \( \Lambda_{\text{RF}} = \sqrt{(\delta_{\text{RF}})^2 + |\epsilon_{\kappa}^\text{RF}|^2} \) and \( \phi_{\text{RF}} = \kappa_{\text{RF}} \theta - \phi_{\kappa} - \pi \) where \( \phi_{\kappa} \) is the phase of \( \epsilon_{\kappa}^\text{RF} \).

\( |\epsilon_{\kappa}^\text{RF}| = 47.2 \times 10^{-6}, \quad \kappa_{\text{RF}} = 5 - Q_{\text{RF}}, \quad Q_{\text{RF}} \approx 0.605 \)

The \( \hat{l}(s) \) and \( \hat{m}(s) \) are chosen so that spins on the CO precess at the uniform rate \( \nu_0 \) in the \((\hat{l}(s), \hat{n}_0(s), \hat{m}(s))\) frame — NOT using \((\hat{x}, \hat{y}, \hat{z})\) \(\rightarrow\) any ring geometry.

Protons, just before the RFD. RFD + forced solution. \( \delta_{\text{RF}} = \pm |\epsilon_{\kappa}^\text{RF}| \)
Include large-amplitude pre-existing vertical betatron motion. — off spin-orbit resonance.

- No misalignments
- $2.1 \text{ GeV/c} \implies \nu_0 = a\gamma_0 = 4.395$
- $Q_y = 3.580, \quad Q_x = 3.543$
- $\kappa^\nu = 8 - Q_y \implies \delta^\nu = \nu_0 + Q_y - 8 = -0.02490...$
- Before cooling, the $3-\sigma$ vertical emittance for protons at 2.1 GeV/c is $2\pi - 4\pi$ mm.mrad.
  For $4\pi$ mm.mrad: $\beta^\text{max}_y \approx 32$ metre $\implies y^\text{max} \approx 11$ mm.
- For this simulation, sit ON the $18\pi$ mm.mrad ellipse and imagine that the motion is still linear.
  Then $y^\text{max} \approx 24$ mm:
  Relax! it’s only a simulation!
Then:

Directions cosines: $n_l$, $n_{m0}$, $n_m$
What’s happening?
The “ground state” has shifted!!! and so has the spin tune – and this is not just naive interference.
The uniform Invariant Frame Field

- $\hat{u}_1(z,s), \hat{n}(z,s), \hat{u}_2(z,s)$ with $\hat{u}_1(z, s + C) = \hat{u}_1(z, s)$ and $\hat{u}_2(z, s + C) = \hat{u}_2(z, s)$

- a local coordinate system attached to each $(z, s)$ to appraise spin motion as particles flow through phase space. No History. Generalises $\hat{l}(s), \hat{n}_0(s), \hat{m}(s)$

- $\hat{u}_1(z,s)$ and $\hat{u}_2(z,s)$ are chosen so that spins precess at a uniform rate.
The proper definition of spin tune and spin-orbit resonance

See “Quasiperiodic spin–orbit motion and spin tunes in storage rings”
Barber, Ellison and Heinemann, PRST-AB, 7, 124002 (2004).

- An ADST $\nu(J)$ describes the rate of uniform spin precession around $\hat{n}$ in a u-IFF. $(\hat{u}_1(z,s), \hat{n}(z,s), \hat{u}_2(z,s))$, where $J$ is the list of 3 amplitudes or, if an external RF field is applied, 4 amplitudes.
- The transform $\hat{u}_1 \pm i\hat{u}_2 \Rightarrow (\hat{u}_1 \pm i\hat{u}_2)\exp\{((j_0 + j \cdot Q)\theta\}$ with $(j_0, j) \in \mathbb{Z} \times \mathbb{Z}^3$ causes the change $\nu(J) \Rightarrow \pm \nu(J) + j_0 + j \cdot Q$.
- This motivates the definition of an equivalence relation where $\nu_1$ and $\nu_2$ in $[0,1)$ are said to be equivalent - and we write $\nu_1 \sim \nu_2$ - iff there exist $(\varepsilon, j_0, j) \in \{-1,1\} \times \mathbb{Z} \times \mathbb{Z}^3$ such that $\nu_2 = \varepsilon \nu_1 + j_0 + j \cdot Q$.
- $\Rightarrow$ The ADST is an equivalence class! – countably infinite in size.
- The system is on spin-orbit resonance if the equivalence class contains 0, i.e. if some $\nu(J) = j_0 + j \cdot Q$.
- The condition $\nu_0 = j_0 + j \cdot Q$ is NOT a spin-orbit resonance condition but the system will be near resonance if some $\nu(J) \approx \nu_0$.
- Systems tend to avoid exact resonance! – see the SRM.
- The ADST does not exist on orbital resonance.
The preferred member of the equivalence class

- The equivalence class is countably infinite
- The member $\nu(J)$ which $\to \pm \nu_0$ as its u-IFF reduces smoothly to $(\hat{I}(s), \hat{n}_0(s), \hat{m}(s))$ – if such a member exists.
- $\Rightarrow$ these $(\hat{a}_1(z, s), \hat{a}_2(z, s))$ are the generalisation of $(\hat{I}(s), \hat{m}(s))$

- The new reference spin tune is the preferred member of the ADST of the new ground state!!
The spin motion for the pre-existing vertical betatron motion?

Just before the RFD

This looks like SRM – expected from experience.
The SRM for vertical betatron motion

\[ \hat{n}^\nu(s, \phi_\kappa) = (\text{sgn } \delta^\nu) \frac{\left( \delta^\nu \hat{n}_0(s) + |\epsilon_\kappa^\nu| \left( \hat{l}(s) \cos \phi_\kappa + \hat{m}(s) \sin \phi_\kappa \right) \right)}{\Lambda^\nu} \]

where \( \Lambda^\nu = \sqrt{(\delta^\nu)^2 + |\epsilon_\kappa^\nu|^2} \) with \( \delta^\nu = \nu_0 - \kappa^\nu \) and \( \phi_\kappa = \theta \kappa^\nu - \phi_\epsilon + \pi \) where \( \phi_\epsilon \) is the phase of \( \epsilon_\kappa^\nu \).

- With \( \delta^\nu = -0.02490 \) and \( \hat{n}_{n_0}^\nu = 0.934 \), \( |\epsilon_\kappa^\nu| \) should be 0.009582.
- This agrees exactly with the value from the Fourier integral.
- \( \hat{n}_{n_0}^\nu = 1/\sqrt{2} \) when \( \delta^\nu = \pm |\epsilon_\kappa^\nu| \) etc etc.

\[ \implies \text{spin motion for the pre-existing vertical betatron motion is well described by an SRM — expected!} \]
The preferred member of the ADST for the SRM

The preferred member of the ADST for the SRM is

\[ \nu(J_y) = -\Lambda' + \kappa' \implies \nu(J_y) - \nu_0 = -\Lambda' - \delta' = -0.001779... \]

The shift is negative!

- The full \( \nu_0 = 4.39498 \) at 2.1 GeV/c
- The shift represents about 2.6 kHz in the original scan range of \( \pm 4 \) kHz!
  \( \implies \) Chao’s “matrix formalism” would not be too relevant.
- **Spectral analysis** of spin motion with Theorem 9.1.c in BEH (2004):
  Lines at \( j_{\nu} \nu(J_y) + j_0 + j_y Q_y : j_\nu \in \{0, 1, -1\} \) The line with \( [\nu(J_y)] = 0.393201... \) is prominent
- The \( Q_{\text{rf}} \) at which spins flip in a Froissart-Stora scan is shifted **upwards** by 0.001779

\[ \Xi = 1 \text{ with } \vec{S} \text{ initially parallel to } \hat{n}' \text{: final average -0.11 instead of -0.264.} \]
Everything is consistent, and with the RFD running such that $\tilde{\delta}_{rf} := \nu(J_y) - \kappa_{rf} = 0$ we get
The $\hat{n}_0$ component of the full ISF

A **surface** so that the ISF is a single valued function of the phases $\phi_{\text{rf}}$ and $\phi_y$ as required.

A very simple form, being very well parametrised by the function

$$\hat{n}_{n_0}(\phi_{\text{rf}}, \phi_y) = (|\epsilon^\chi|/\Lambda^\chi) \cos\{[(\phi_{\text{rf}} - \phi_y)/2\pi]\}$$
Now view within the u-IFF of the pre-existing vertical betatron motion

An SRM within an SRM!

\[
\hat{n}_{\text{full}}(\phi, \phi_{rf}) = \frac{(\tilde{\delta}_{rf} \hat{n}_{\nu} + |\tilde{\epsilon}_{\kappa}^{rf}|(\hat{u}_{1} \cos \tilde{\phi}_{rf} + \hat{u}_{2} \sin \tilde{\phi}_{rf}))}{\tilde{\Lambda}^{rf}},
\]

\(\tilde{\epsilon}_{\kappa}^{rf}\) is the resonance strength in the u-IFF, and \(\tilde{\Lambda}^{rf} = \sqrt{(\tilde{\delta}_{rf})^2 + |\tilde{\epsilon}_{\kappa}^{rf}|^2}\), and \(\tilde{\delta}_{rf} = \nu(J) - \kappa_{rf}^{rf}\)

What is \(|\tilde{\epsilon}_{\kappa}^{rf}|\)???

We naively expect:

\(|\tilde{\epsilon}_{\kappa}^{rf}| \leq |\epsilon_{\kappa}^{rf}|\) since \(\hat{n}_{\nu}\) is tilted from the vertical while the perturbing fields are horizontal.
Three tests

- With \( |\tilde{\delta}_f| = |\tilde{\epsilon}_\kappa| = f|\epsilon_\kappa| = 0.901 |\epsilon_\kappa| \rightarrow \hat{n}^{\text{full}} \cdot \hat{n}^\nu = 1/\sqrt{2} \) etc etc

- The Froissart-Stora formula describes the level of adiabatic invariance of \( \tilde{S} \cdot \hat{n} \)
A scan with \( \tilde{S} \) initially parallel to \( \hat{n}^\nu \) and observing the final \( \hat{n}^{\text{full}} \cdot \hat{n}^\nu \) i.e. a F-S scan within the u-IFF. For \( f = 0.901 \)

\[
\begin{align*}
|\tilde{\epsilon}_\kappa| = 0.901 |\epsilon_\kappa|
\end{align*}
\]

A scan with \( f = 1.0 \) gives a bad fit.

- With the RFD included at various \( Q_{\gamma f} \) the “preferred member of the ADST” in the u-IFF (instead of in \( (\hat{l}, \hat{n}_0, \hat{m}) \) frame) should be:

\[
\nu^{\text{full}} = (\text{sgn} \tilde{\delta}_f) \tilde{\Lambda}^{rf} + \kappa^{rf} = (\text{sgn} \tilde{\gamma}_f) \tilde{\Lambda}^{rf} + \nu(J_y) - \tilde{\delta}^{rf}.
\]

Spectral analysis of spin motion including the RFD:

With **Theorem 9.1.c in BEH (2004)**, the observed spectra require that \( |\tilde{\epsilon}_\kappa| = 0.901 |\epsilon_\kappa|\)
Now some fun with spinors

The Pauli matrices and spinors (NOT wavefunctions!):

\[
\sigma_l = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_{n_0} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \sigma_m = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \tilde{S} = \Psi^\dagger \sigma \Psi
\]

With two dominant harmonics in \( \bar{\omega}(z, s) \cdot (\hat{l}(s) - i\hat{n}(s)) \):

\[
\frac{d\Psi}{d\theta} = -\frac{i}{2} \begin{pmatrix} -\nu_0 & -i(\epsilon^\nu_\kappa)^* \exp(i\kappa^\nu \theta) - i(\epsilon^r_\kappa)^* \exp(i\kappa^r \theta) \\ i\epsilon^\nu_\kappa \exp(-i\kappa^\nu \theta) + i\epsilon^r_\kappa \exp(-i\kappa^r \theta) & \nu_0 \end{pmatrix} \Psi
\]

Then with a sequence of unitary transformations into the u-IFF (Maple):

\[
\frac{d\Psi_{\text{upper}}}{d\theta} = -\frac{i}{2} (\mathcal{M}_{\text{res}} + \mathcal{D} + \mathcal{N}) \Psi_{\text{upper}},
\]

\[
\mathcal{M}_{\text{res}} = \begin{pmatrix} -\nu(J_y) & -i(\epsilon^r_\kappa)^* \exp(i\kappa^r \theta) \\ i\epsilon^r_\kappa \exp(-i\kappa^r \theta) & \nu(J_y) \end{pmatrix},
\]

with (\( \mathcal{D}, \mathcal{N} \)) oscillating but far off resonance and with (\( \mathcal{D}, \mathcal{N} \)) \( \to 0 \) as the component \( \hat{n}_{n_0}^\nu \to 1 \)

\[
|\epsilon^r_\kappa| = \frac{(1 + \hat{n}_{n_0}^\nu)}{2} |\epsilon^r_\kappa|_{\bar{\delta} = 0} = 0.967 \times |\epsilon^r_\kappa|_{\bar{\delta} = 0} \quad \text{for} \quad \hat{n}_{n_0}^\nu = 0.934
\]

BUT, \( |\epsilon^r_\kappa|_{\bar{\delta} = 0} = 0.930 \times |\epsilon^r_\kappa|_{\bar{\delta} = 0} \implies |\epsilon^r_\kappa| = |\epsilon^r_\kappa| = 0.899 \times |\epsilon^r_\kappa|_{\bar{\delta} = 0} \implies f = 0.899 \) !!
...and some serious stuff with COSY

- If spin motion for pre-existing vertical betatron motion is described by an SRM and $|\epsilon^\gamma_\kappa|$ is known, we know the preferred member of the ADST.

- At fixed $|\epsilon^\gamma_\kappa|$: $|\nu(J_y) - \nu_0| = | - \Lambda^\gamma - \delta^\gamma|$ increases as $|\delta^\gamma|$ decreases.

- Measurements of resonance strengths for protons were made at $Q_y = 3.6 \implies \delta^\gamma = -0.0050$.

- Then if $|\epsilon^\gamma_\kappa|$ is insensitive to $Q_y$, $\nu(J_y) - \nu_0 = -0.00158$ ON the ellipse with 3.6 mm.mrad. $\implies y_{\text{max}} \approx 10.7$ mm.

- Two parameters: the preferred member of the ADST for the pre-existing vertical betatron motion $\nu(J)$ and the attenuation $f$.

**Suggestion**

- Run at $Q_y = 3.6$ and 2.1 GeV/c with polarised protons.

- Cool the beam to get a $3-\sigma$ vertical emittance of $\approx 0.3$ mm.mrad.

- Use a vertical kicker to put the beam onto ellipses in the range $0 - 3.6$ mm.mrad.

- Use the field of the RF solenoid as a probe to measure $\nu(J_y) - \nu_0$ by measuring the RF tune needed to get zero time averaged vertical polarisation in each case and check the dependence of $\nu(J_y) - \nu_0$ on $J_y$ against the expectation.

- Or run at $Q_y = 3.58$ and $a_\gamma \sigma_0 = 4.4148$....
Why?

(1) Because it’s never been done.
(2) Because the literature on spin tune shifts contains too much mumbo-jumbo.
(3) Because COSY is perfectly placed and has a very experienced crew.
(4) Because people wanting to measure beam energies very precisely might want to have a better understanding of the systematics. See (2).
(5) Etc.....

Questions:

- Is it feasible to put the beam on the ellipse? See DESY 09-15 – in preparation.
- Can the energy spread be kept low enough? Orbit length?
- How long does the beam stay on the ellipse (non-linear motion, scattering in the polarimeter, IBS, space charge, image forces...)?
- How can the phase space distribution be measured for checking that the particles are on/off the ellipse?
- If it’s only a short time, is it feasible to set up an injection/measurement routine that can deliver enough precision?
- Etc.

⇒ Homework for the COSY crew.

In simple rings the shifts might be bigger at higher energies – we need large $|\varepsilon_\kappa|$
Summary

- Going beyond the common perception that non-spin-resonant background vertical betatron motion is not too interesting.

- With appropriate computational tools:
  - Stroboscopic averaging to get the ISF in general situations without models,
  - Efficient spin-orbit tracking
  - Spectral analysis

- and clearly defined mathematical concepts with theorems (rigour). E.g. the proper definition of the ADST based on conventional mathematics!

  \[ \Rightarrow \textbf{Efficient analysis}. \]

- The resonance strength for the RFD \textbf{does} depend on the coordinate system

\[ \Rightarrow \text{AND} \]

  \[ \Rightarrow \text{A suggestion for a test using COSY, a perfect facility with its experts.} \]

  \[ \Rightarrow \text{A chance to clean up this business of spin tune shifts.} \]
  
  Confusions, ignorance and laziness about such shifts in the literature.

When you get too old to hunt, you teach a course on how to read buffalo shit.

(Eldon Dedini: The Tracker Magazine 1985.)
