# 1 Introduction.

## 1.1 Parton model.

Parton model has been formulated by Richard Feynman in 1969. In this model we can study high energy collision between hardons and photons or leptons. Parton model discribes particles like protons or neutrons as a more complex objects. According to this model we can interpret deep inelastic scattering as scattering process of lepton on quasi free praticles, called parton.

## 1.2 Deep inelastic scattering.

Deep inelastic scattering of electrons on protons

$$ep \rightarrow eW \quad (1)$$

has been central to exploration of proton structure and quark-gluon dynamic as described by perturbative Quantum Chromo Dynamics (pQCD).

Figure 1: Deep inelastic scattering.

Intresting fact is that in scattering procces  $W$ , which is hadronic mass, is always bigger than mass of the incoming proton. When the four momentum of the virtual photon (  $Q^2$  ) is much bigger than proton mass we can name it deep inelastic scattering.

## 1.3 Monte Carlo simulation.

Monte Carlo generators, which are based on QCD models, simulate deep inelastic scattering interaction and give full information about all particles as four momenta forming a final state. It provides us with theoretical predictions for experimental measurement, which is especially important in this area of phase space where calculations don't exist or can't be used. This programs can also estimate hadronic corrections.

Figure 2: Schematic representation of MC generator in e-p collision. ME - matrix element PS - parton shower ( multiparton radiation)

In generation of e-p collision events we can feature three steps, which are shown in fig 2:

- Precise calculations QCD matrix element in leading order for hard process.
- Simulation of parton cascade from initial state.
- Modeling of final state: simulation parton cascade from final state and nonperturbative hadronization.

#### 1.4 Rapgap and pythia 8 event generators.

In my project I worked on two MC event generators (pythia 8 and rapgap). The most important difference between this two generators is that rapgap generator was specially developed to describe e-p collision in DIS but pythia is a general purpose generator which has no dedicated development for DIS. Because parton shower have become a standart component in the description of high energy collision we tested two different approaches in pythia 8: default shower and new, dipole recoil.

Figure 3: Default shower approach.

Figure 4: Dipole recoil approach

The difference between this to approaches we can illustrate in figure 3 and figure 4. Incoming parton in both approaches is the same but the important difference is that outgoing parton in default shower has  $k_T$  not equal 0 as in dipole recoil. Another essential point, there is one incoming parton and it splits into two partons in default shower but in dipole recoil approach which is actually scattering process, we have two partons coming in and it produce three outgoing partons.

### 1.5 $F_2$ structure function.

DGLAP evolution equations let us calculate parton distribution dependent of  $Q^2$  and also  $Q^2$  evolution of structure function  $F_2$ . If we know input parton distribution in  $x$  for initial scale  $Q^2$  we can make a prediction of  $F_2$  function at larger value of  $Q^2$ . Comparing prediction of pQCD with a result of measurement structure function of proton  $F_2$  in deep inelastic scattering of lepton on nucleons was one of the first and most important test of quantum chromodynamics. Structure function  $F_2$  can be expressed as a density of quarks and anti-quarks. In general,  $F_2$  function is given by this formula:

$$F_2(x, Q^2) = x \sum_i e_i^2 [q_i(x, Q^2) + \bar{q}_i(x, Q^2)] \quad (2)$$

## 2 Project

In my project we simulated higher order corrections with parton shower, which is multiparton radiation, which can be also used to define a transverse momentum dependent parton density.

### 2.1 $F_2$ distribution function with old measurement of inclusive DIS

At the beging we make a prediction for  $F_2$  structure function for old measurement, that is H1 from 1996[1], with two different MC event generators: rapgap

and pythia 8. To observe impact of parton shower on  $F_2$  distribution we generate prediction with different kind parton shower (initial parton shower, final parton shower) and also without parton shower. All predictions were generated in wide range of  $Q^2$  (from  $1.7\text{GeV}^2$  to  $70000\text{GeV}^2$ ).

### 2.1.1 Result for pythia 8

In figure 5, there is a exemplary histogram of  $F_2$  distribution made with pythia generator for  $Q^2 = 15\text{GeV}^2$  with default shower. The interesting thing it that we can observe significant effects for  $F_2$  distribution generated with initial parton shower which motivated us to go further into this topic.

Figure 5: Prediction of  $F_2$  function structure generated with default shower approach compared to data[1].

In figure 6, there is again a exemplary histogram of  $F_2$  distribution made with pythia 8 event generator for  $Q^2 = 15\text{GeV}^2$  but with dipole recoil approach. There is clearly visible that prediction with dipole recoil approach describe data better than prediction with a default shower.

Figure 6: Prediction of  $F_2$  function structure generated with dipole recoil approach compared to data[1].

### 2.1.2 Result for rapgap

To observe impact of parton shower in other MC event generators we made a prediction of  $F_2$  distribution also with rapgap generator for old measurement. In figure 6, there is histogram made with rapgap for  $Q^2 = 15\text{GeV}^2$  with all kind of parton shower. As expected rapgap generator give us much better agreement with data than pythia 8.

Figure 7: Prediction of  $F_2$  function structure compare to data[1].

## 2.2 $F_2$ distribution function with new measurement inclusive DIS

The next step of my project was preparing analysis routine for new data, that is H1 + ZEUS, including HERA 1 and HERA 2 [2]. Format of HEP data wasn't

usable in Rivet (analysis tool) so we had to export data from txt file to special file, required in Rivet. To better see result we needed to split a data in smaller ranges. Doing this by hand would be too much time-consuming so we made a simple c++ program which can automatically split data, calculate x errors and export from txt format to yoda format at once.

### 2.2.1 Result for pythia 8

In figure 8, there is prediction of  $F_2$  distribution for new measurement generated with initial parton shower and without parton shower. This distribution was made with pythia event generator for  $Q^2 = 15\text{GeV}^2$  with default shower approach. As expected, the prediction obtained with initial parton shower does not describe data well.

Figure 8: Prediction of  $F_2$  function structure generated with default shower compared to data[2].

Prediction of  $F_2$  distribution for new measurement with dipole recoil approach describes data even better than for old data which confirmed that dipole recoil approach is more suitable for parton shower.

Figure 9: Prediction of  $F_2$  function structure generated with dipole recoil approach compared to data[2].

### 2.2.2 Result for rapgap

We also generate prediction of  $F_2$  structure function for new measurement with rapgap event generator and again we get nice prediction compare with most of data points. Exemplary result for  $Q^2 = 15\text{GeV}^2$  it shown at figure 10. In this case prediction looks a little bit worse compare to prediction made with pythia 8 with dipole recoil approach.

Figure 10: Prediction of  $F_2$  function structure compare to data[2].

### 2.3 Prediction for $k_T$

To better understand why parton shower have a large impact on  $F_2$  distribution we decide to compare a prediction of two different  $k_T$ , the transverse momentum of propagator parton. First  $k_T$  is intrinsic  $k_T$  and the second is a  $k_T$  generate

with initial parton shower. Figure 11 illustrates the difference between  $k_{T1}$  and  $k_{T2}$

Figure 11: Difference of  $k_{T1}$  and  $k_{T2}$

### 2.3.1 Result of prediction for $k_T$ .

As expected we can't observe significant difference between  $k_T$  prediction generated with initial parton shower and without parton shower for intrinsic  $k_T$ , shown in figure 12.

Figure 12: Prediction of  $k_{T1}$ .

However there is large difference in  $k_{T2}$  distribution. In figure 13, there is

clearly visible the difference between  $k_T$  generated with initial parton shower and without parton shower. This difference makes us to apply special treatment in prediction of  $F_2$  distribution generated with parton shower.

Figure 13: Prediction of  $k_{T2}$ .

### 3 Summary

Parton shower effect is really important in prediction for  $F_2$  structure function. In my project we have shown explicitly how significant parton shower effect in inclusive deep inelastic scattering is. We also prove that there is special treatment needed to apply parton shower in deep inelastic scattering. We have shown the difference between dipole recoil and default shower in pythia 8 as well.
