

Wire scanner measurements in the FLASH undulator

Florian Loehl, Eduard Prat
XFEL Beam Dynamics Meeting, 15 January 2007

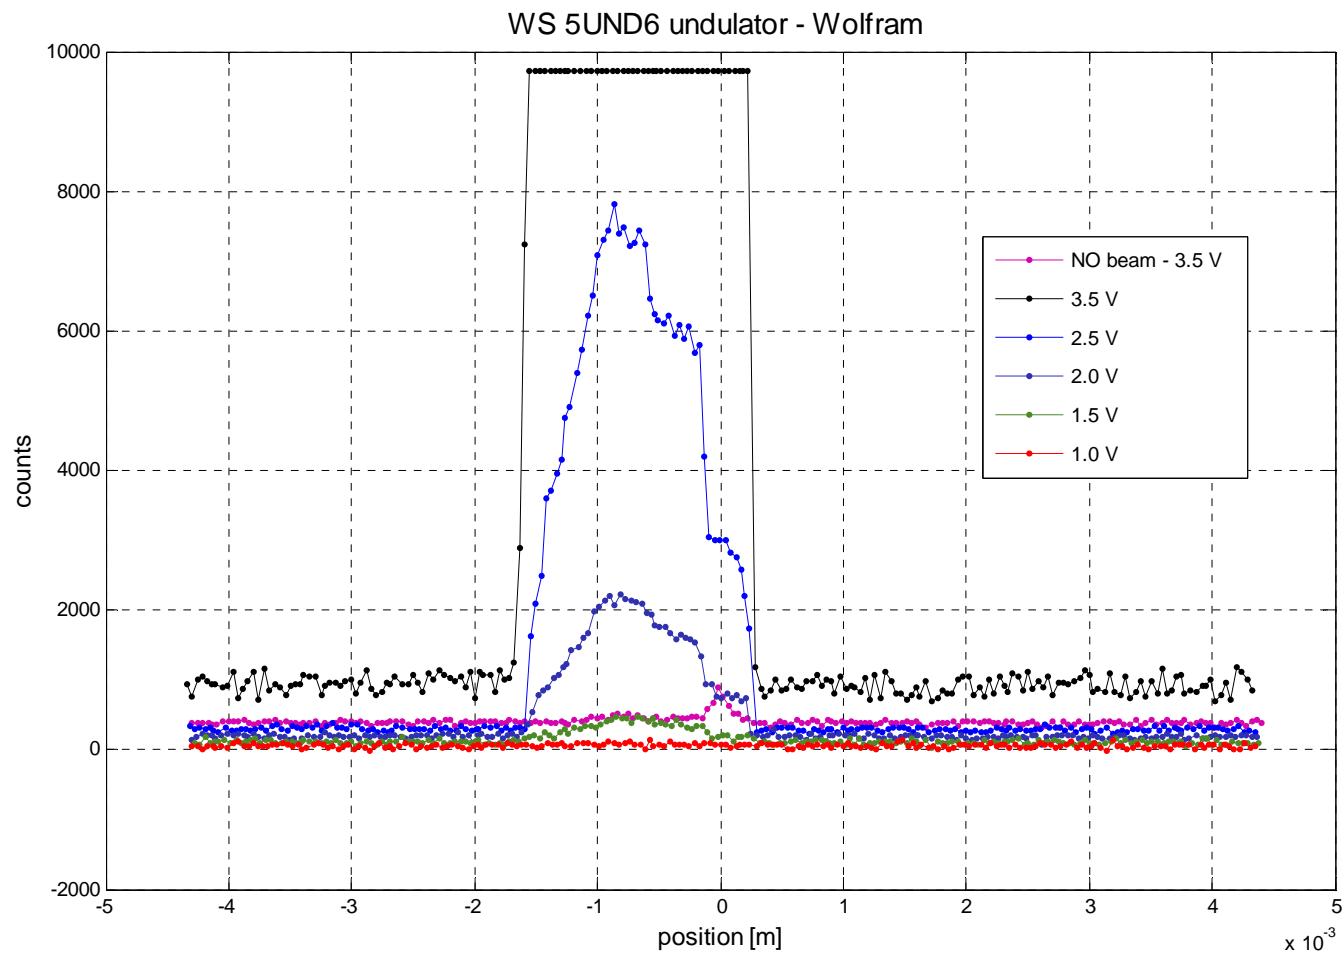

- There are 3 different wires:
 - 50 µm Tungsten (the one we have been using all the time)
 - 10 µm Tungsten
 - 10 µm Carbon

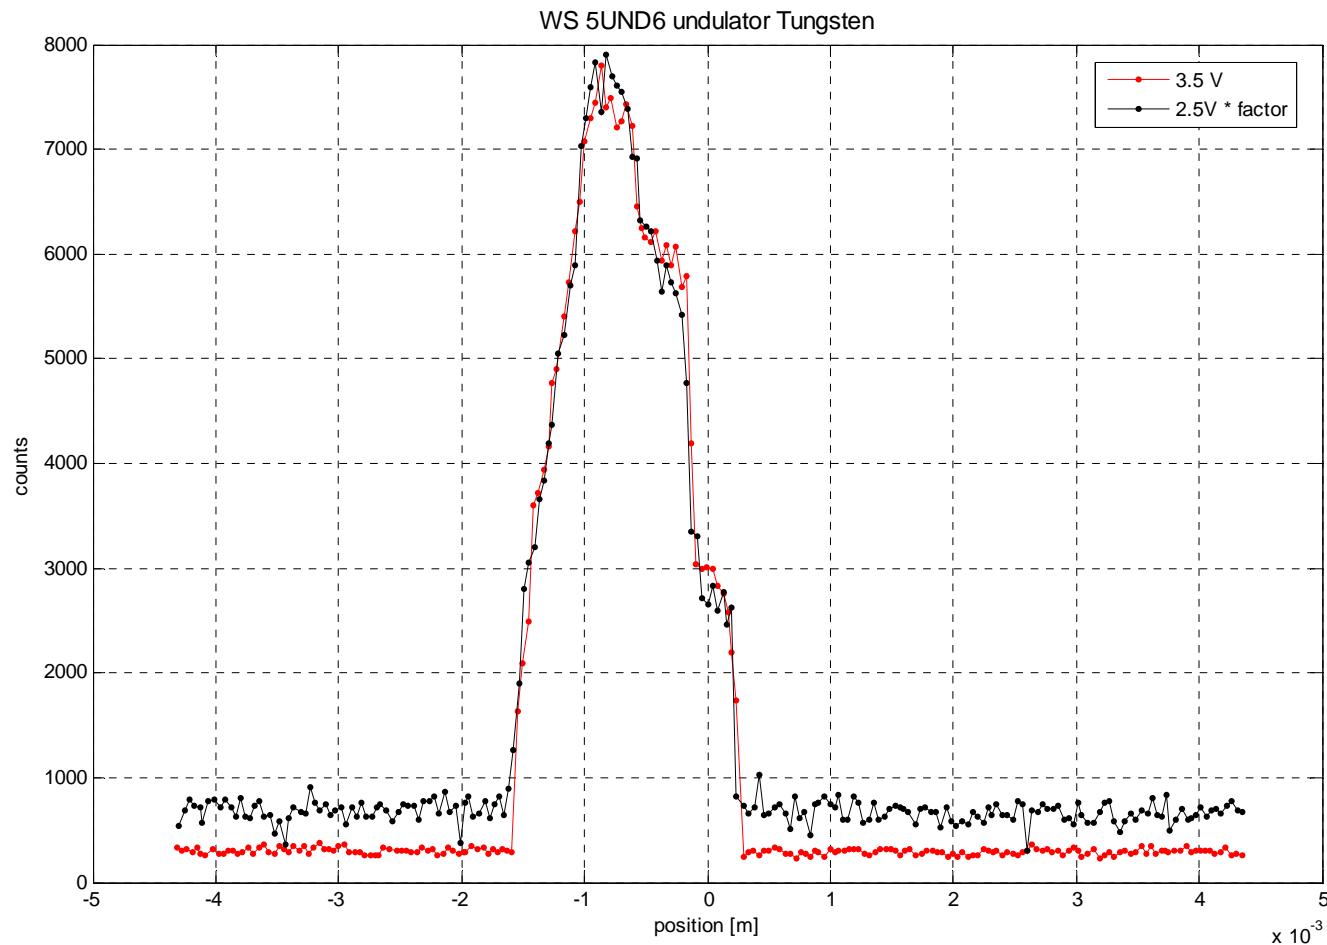

✓ We have scanned horizontally the different wires at 5UND6 with different voltages (~15 scans in ~ 1 hour)

Emittance measurements at FLASH

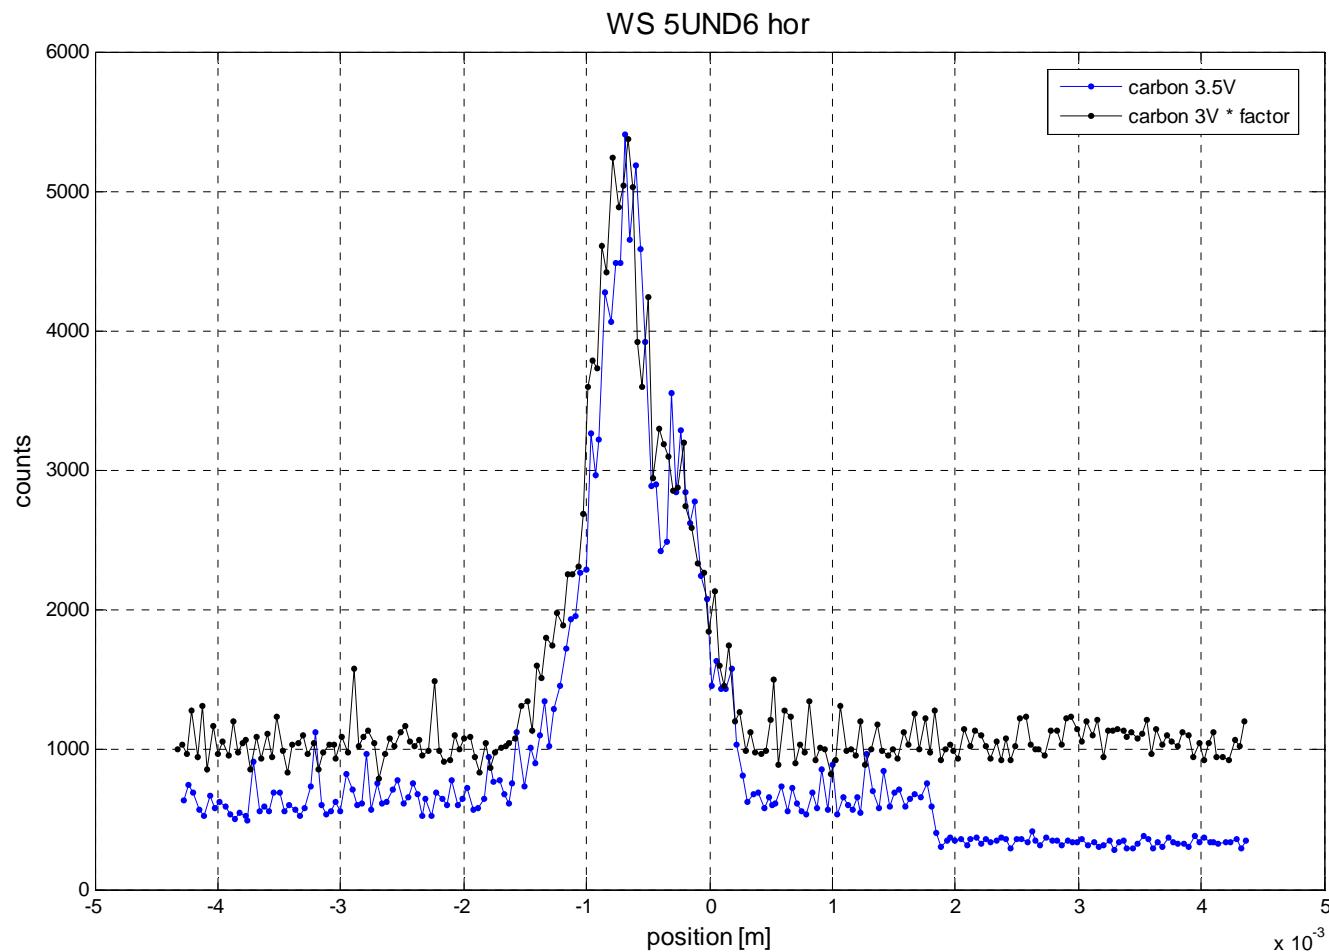

- Before December 06:
 - Emittance increase from DBC2 to undulator by a factor from 2 to 4 or imaginary emittance in the undulator
 - Not possible to match the optics in the undulator
- Preliminary results from December 06
 - Emittance conservation from DBC2 to SEED section
 - Same problem in the undulator as before: imaginary values or emittance increase (now from SEED!), ...

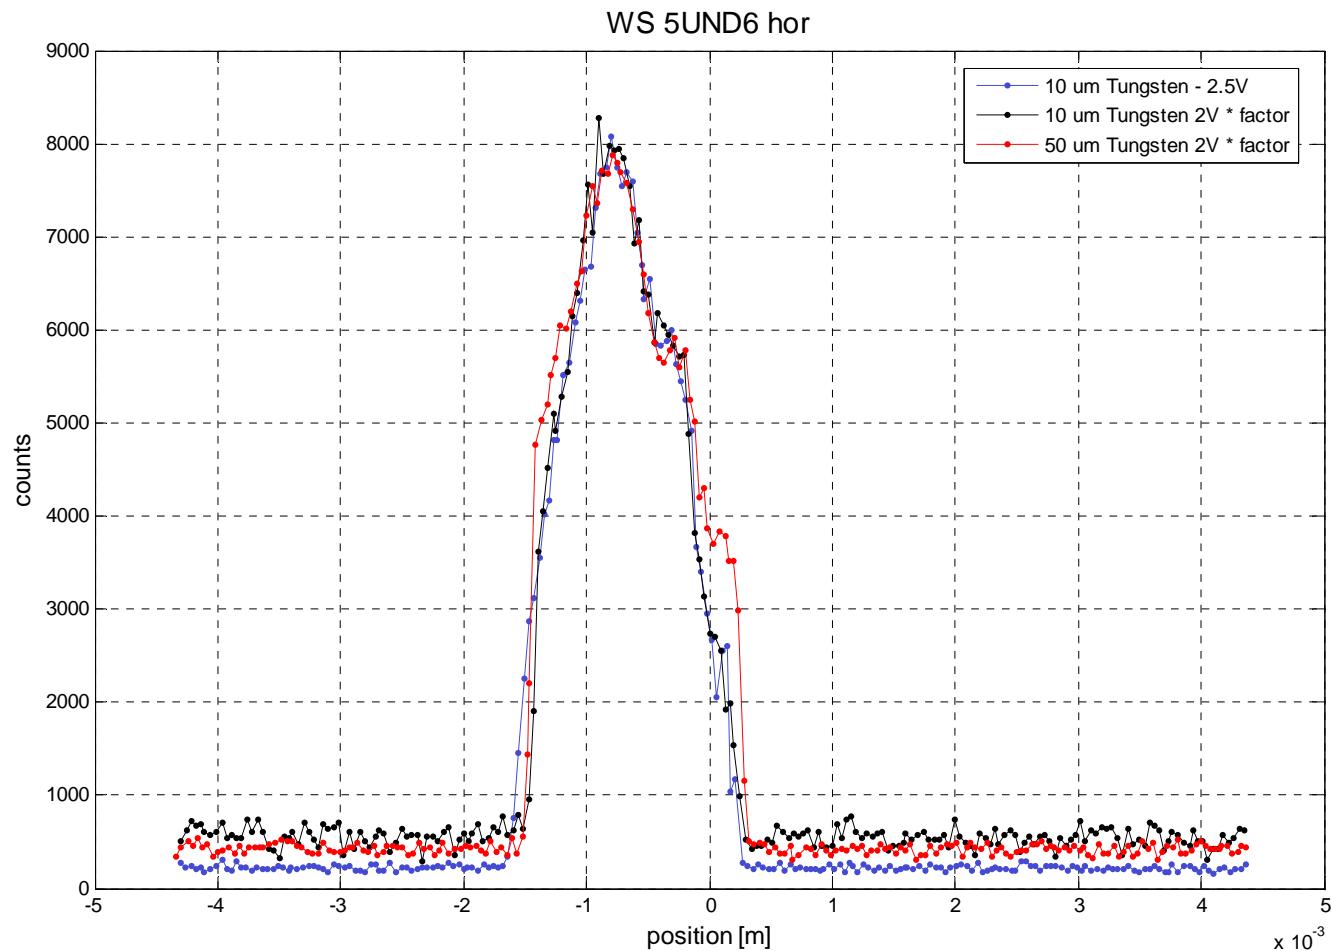

10 μ m Tungsten wire for different voltages

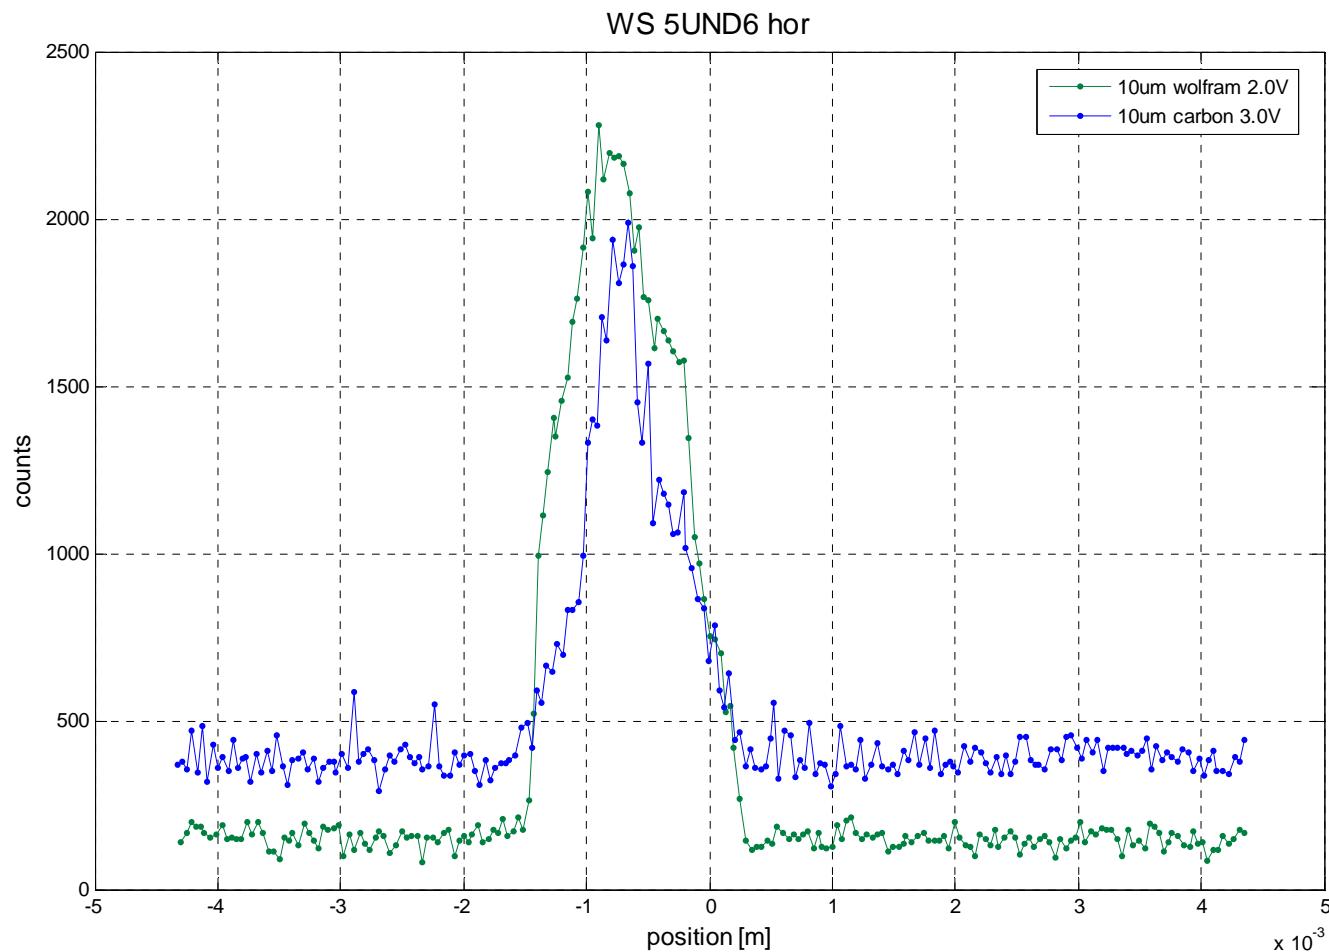

10 μm Carbon – 3.0 & 3.5 V

10 & 50 μm Tungsten

Tungsten 10 μ m vs carbon

- Different voltages for the same wire give reasonable results
- Different wires give different beam sizes
(Specially Tungsten vs Carbon)

One possible explanation: non linear behaviour of the photomultipliers
