

# Particle Physics for Cosmologists: The Program of the International Linear Collider

Jenny List  
DESY

XLIst Rencontres de Moriond

La Thuile, March 18-25, 2006

# Outline

1. Introduction:  
The Physics Case for the ILC
  2. The accelerator, timeline
  3. Physics Examples:
    - 3.1. The Higgs Profile (SM & SUSY)
    - 3.2. The Cosmological Connection
  4. Summary
- Topics **not** covered today:  
SUSY, SM precision measurements, GigaZ,  
Photon Collider Option, Detector R&D, .....

# 1. Introduction: The Physics Case for the ILC

# The Standard Model of Particle Physics

- A unified and precise (0.1%) description of all known subatomic phenomena
- Down to  $10^{-18}$  m
- Back to  $10^{-10}$  s after the Big Bang
- Consistent at the quantum loop level

# Standard Model Deficiencies

- The Higgs particle - required to give masses to force carriers and matter constituents - has not yet been observed
- 25 or so free parameters: masses, couplings, mixing angles, which are not explained
- General stability / fine tuning problems above  $\sim 1$  TeV (stability of Higgs mass, hierarchy of scales)
- Gravity is not included
- and .....

# What is the world made of?

# 21<sup>st</sup> century physics

Fundamental questions on matter, energy, space and time:

- What is the universe made of?
  - What is dark energy? Maybe a 22<sup>nd</sup> century question...
  - What is dark matter?
  
- How do particles acquire mass?
  - Is there a Higgs boson? Or something else taking its role?
  - What is the origin of electroweak symmetry breaking?
  
- Do the fundamental forces unify?
- How does gravity tie in?
- Origin of matter-antimatter asymmetry?

# New physics around the corner

- We expect fundamental answers at the TeV scale
- I.e. from the immediate generation of new colliders
- For theoretical reasons:
  - SM w/o Higgs is inconsistent above  $\sim 1.3$  TeV
  - Fine-tuning problem if nothing between  $m_W$  and  $m_{\text{Planck}}$  - must be near  $m_W$  to be relevant
- For experimental reasons
  - Electroweak precision data want Higgs - or "something in the loops" - below 250 GeV
  - Cosmology wants a dark matter particle with a few 100 GeV

Also:  
 $2m_{\tau} = 350$  GeV  
 $\nu = 246$  GeV

# Hadron and electron machines

... are complementary like X-rays and microscope

$e^+$  • •  $e^-$

- Proton (anti-) proton colliders:
  - Energy range higher (limited by magnet bending power)
  - Composite particles, different initial state constituents and energies in each collision
  - Hadronic final states difficult
- Discovery machines
- Excellent for some precision measurements

- Electron positron colliders:
  - Energy range limited (by RF power)
  - Point-like particles, exactly defined initial state quantum numbers and energies
  - Hadronic final states easy
- Precision machines
- Discovery potential, but not at the energy frontier

# ILC Physics Case (I)

- Whatever the discoveries at the LHC will be - an  $e^+e^-$  collider with 0.5 - 1 TeV energy will be needed to study them
- Example: electroweak symmetry breaking
  - Light Higgs: verify the Higgs mechanism
  - Heavy Higgs: dito, and find out what's wrong in EW precision data
  - New particles: precision spectroscopy
  - No Higgs, no nothing: This is beyond SM! find out what is wrong, and measure the indirect effects with max precision
- Case has been worked out and well documented (e.g. TESLA TDR)
- See also answers to ITRP questions: [hep-ph/0411159](http://hep-ph/0411159)

## ILC Physics Case (II)

- New physics at the origin of electroweak symmetry breaking is expected to be discovered at the next generation of collider experiments
- The case for an  $e^+ e^-$  collider with 500 GeV - 1 TeV energy rests on general grounds and is excellent in different scenarios.
- Cosmological arguments favour this energy region, too.
- The ILC case holds independent of LHC findings; LHC and ILC complement each other.

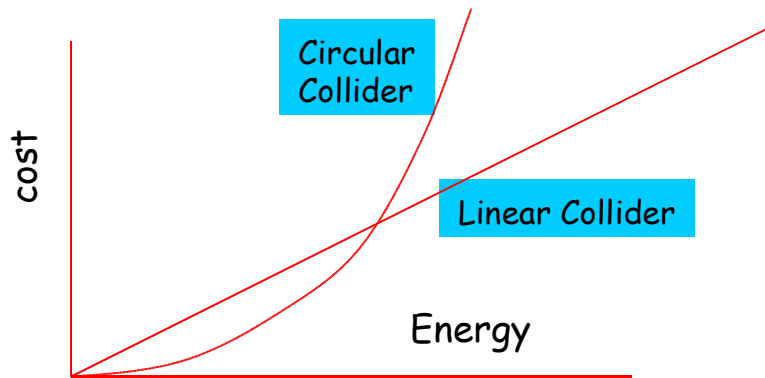

## 2. Accelerator

(a fascinating topic in itself;  
here only a few key issues)

# Linear vs. circular

- Synchrotron radiation
  - $\Delta E \sim (E^4 / m^4 R)$  per turn; 2 GeV per beam at LEP2 (200 GeV)
- Cost
  - circular  $\sim a R + b \Delta E \sim a R + b (E^4 / m^4 R)$ 
    - Optimization  $R \sim E^2 \Rightarrow \text{Cost} \sim E^2$
  - linear  $\sim L$ , where  $L \sim E$

From J.Brau

SLC at SLAC: 100 GeV

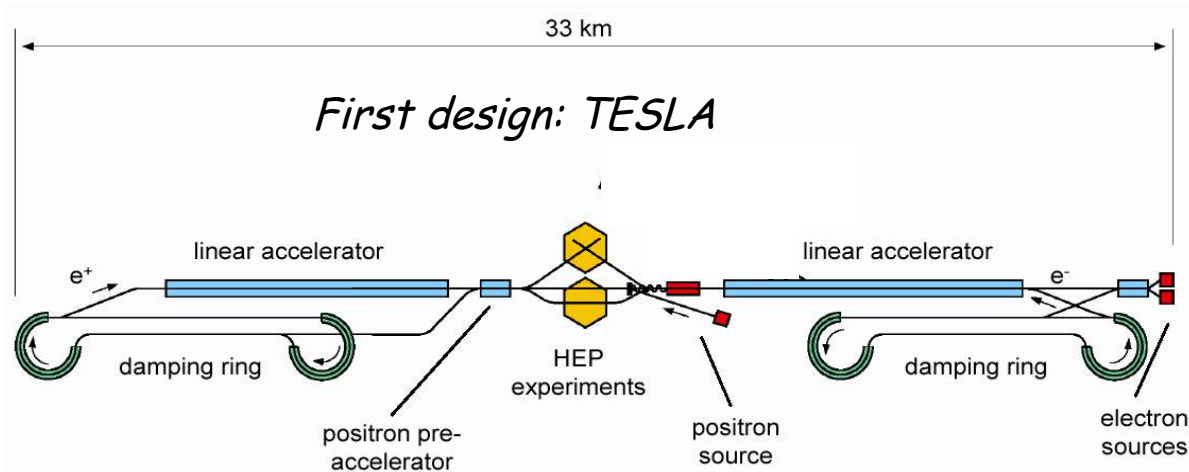

# The Linear Collider Consensus

*The next big machine:*

- $200 \text{ GeV} < \sqrt{s} < 500 \text{ GeV}$  tunable
- Integrated luminosity  $\sim 500 \text{ fb}^{-1}$  in 4 years
- Upgrade to 1 TeV
- Polarisation  $e^-$ : 80% ( $e^+$ : 60%)
- 2 interaction regions
- Concurrent running with the LHC

# Luminosity

- $1/s$  calls for high luminosity

1% precision - 10'000 events  
 for cross-section of 20 fb  
 and integrated luminosity of  $500 \text{ fb}^{-1}$   
 = 100 days at  $5 \cdot 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$

# ILC History

- worldwide project
  - 1990ies: development of several LC projects (500 GeV baseline)
  - 2001: publication of the TESLA TDR:  
the first fully costed, worked out design
  - 2001-2004: competition between „warm“ and „cold“ technology,  
i.e. accelerating structures normal or superconducting
  - 2004: international agreement to use the superconducting  
technology for the ILC
  - 2005: formation of the Global Design Effort (GDE), director  
Barry Barish, Caltech
  - end 2005: definition of the new baseline for the accelerator

up-to-date information on the ILC: <http://www.linearcollider.org/>

# The quest for high gradients

- main building block: superconducting cavities a la TESLA
- chosen because of:
  - energy efficiency
  - less stringent alignment tolerances
  - in operation at TTF
- **Stage 1:**
  - 500 GeV CMS energy
  - mean gradient 31.5 MV/m
  - length per linac 10 km
  - total length 25 km
- **Stage 2:**
  - 1000 GeV CMS energy
  - mean gradient 35 MV/m
  - total length 40 km

# ILC baseline

baseline configuration of the machine:

currently being worked out in international collaboration  
follow this online at <http://www.linearcollider.org/wiki>

Goal: define the baseline at the end of 2005 ✓

do a costing and design during 2006

do a full engineering till 2008:

**Technical Design Report**

ILC 500  
baseline

# ILC Machine - Summary

- The design for a superconducting linear collider with 0.5 - 1 TeV centre-of-mass energy is being worked out in a truly worldwide effort.
- The schedule is ambitious: be ready for approval by the end of the decade - when first LHC physics comes in.
- The demand for precision, for highest luminosity drives the machine design - and challenges the experiments.

## 3. Physics Examples:

### 3.1. The Higgs Profile (SM & SUSY)

# The Higgs particle

- The last missing ingredient to the Standard Model
- Essential to keep theory finite
- Weak gauge bosons and all quarks and charged leptons are originally massless; they acquire mass through interaction with the Higgs field

- New form of matter: fundamental scalar field
- A new force which couples proportional to mass

# Higgs discovery

- At the LHC after about 1 year
- Measure some properties
  - Mass
  - Ratios of couplings
- 1 year LHC = 1 day LC
  - LC can **discover** Higgs-like particle even if rate is 1/100 of SM

# Higgs at the ILC

- Measure the Higgs profile
  - Mass and width
  - Quantum numbers
  - Couplings to fermions
  - Couplings to gauge bosons
  - Self coupling
- Convince ourselves that the Higgs is the Higgs
  - Establish the Higgs mechanism
- Do Higgs precision physics
  - Deviations from SM, admixtures, SUSY Higgs

# Higgs production

- Higgs strahlung and WW fusion

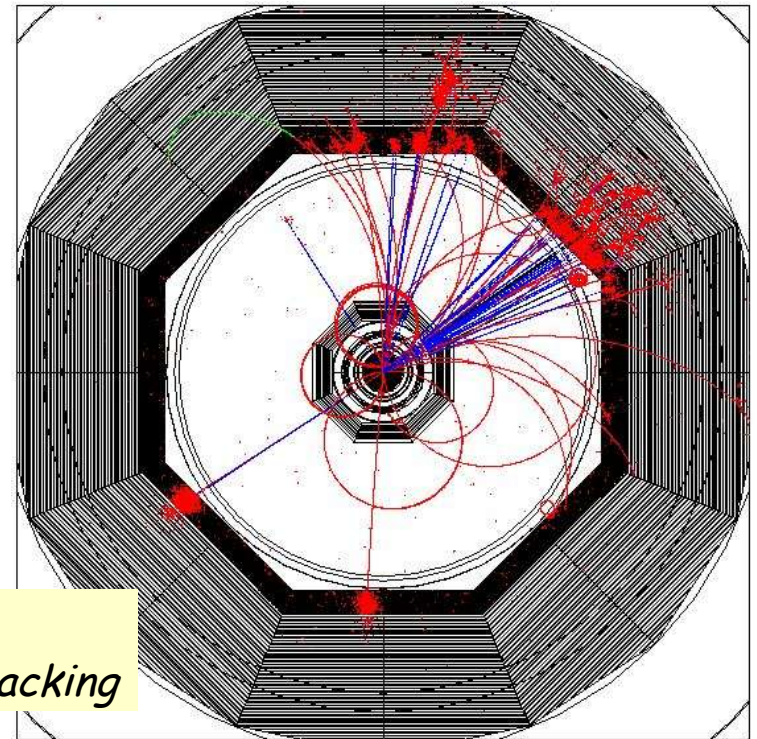

# Higgs signature

- find the Higgs independent of decay mode
- via recoil mass - only at ILC!

*Requires excellent tracking*

- Provides absolute normalization for decay rates

# Higgs mass

- Use kinematic constraints
  - Detector resolution still matters
- Precision below 0.1%

$M_H$ (GeV)	Channel	$\delta M_H$ (MeV)
120	$llqq$	$\pm 70$
120	$qqbb$	$\pm 50$
120	Combined	$\pm 40$
150	$ll$ Recoil	$\pm 90$
150	$qqWW$	$\pm 130$
150	Combined	$\pm 70$
180	$ll$ Recoil	$\pm 100$
180	$qqWW$	$\pm 150$
180	Combined	$\pm 80$

# The Higgs boson total width

- For large  $M_H$  use line shape
- for low  $M_H$  from  $\sigma$  (WW fusion) and  $BR(H \rightarrow WW^*) = \Gamma_{H \rightarrow WW^*} / \Gamma_{total}$

*Needs excellent jet energy resolution*

- gives access to all couplings

# Higgs boson couplings

- The Higgs mechanism at work
  - coupling  $\sim$  mass
- $HWW$ ,  $HZZ$ : production cross section
- Yukawa couplings to fermions
  - Most challenging: disentangle  $bb$ ,  $cc$  and  $gg$
  - Beauty and charm tagging

*Requires excellent vertex detector*

*Higgs branching ratios (absolute!)*

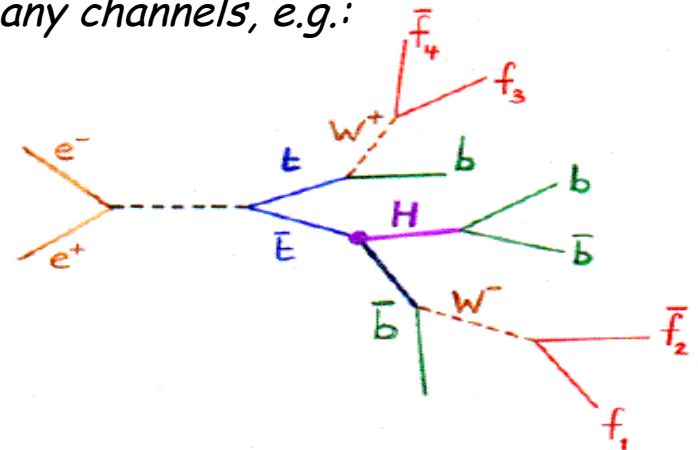

# Top Yukawa coupling

- Example for LHC  $\oplus$  LC synergy: Common interpretation:  
 absolute top Yukawa coupling from  
 $gg, qq \rightarrow ttH$  ( $H \rightarrow bb, WW$ ) (@LHC) (rate  $\sim (g_t g_{b/W})^2$ )  
 and  
 $BR(H \rightarrow bb, WW)$  (@LC) (absolute measurement of  $g_{b/W}$ )

At the ILC (alone), need highest energy and combine many channels, e.g.:

# Top mass

- Best method: threshold scan at the ILC
- Presently largest source of uncertainties for calculation of many SM observables
- Precision 50-100 MeV (currently  $\sim 2300$  MeV, LHC  $\sim 1000$  MeV)
- width to 3-5%

# The Higgs self-coupling

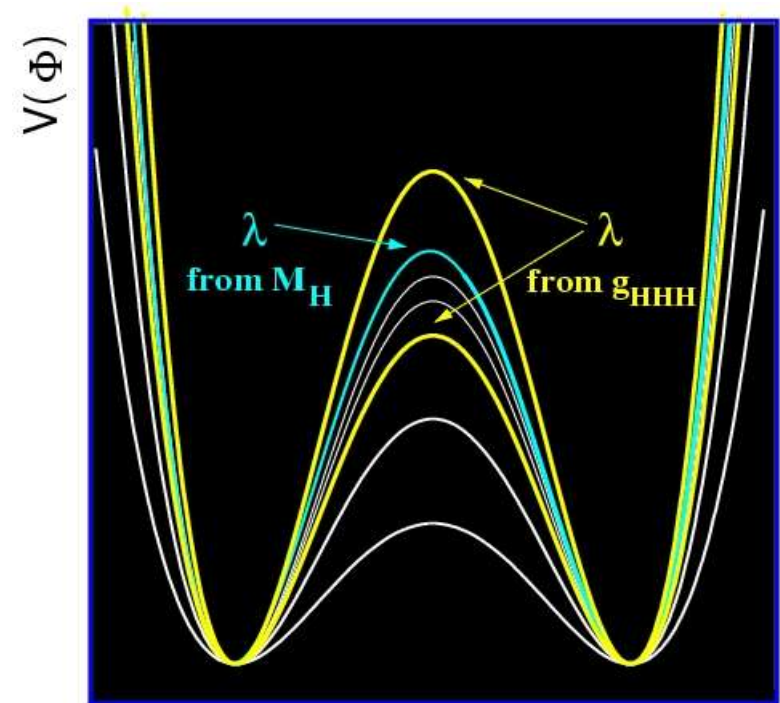

- *Is the Higgs the Higgs?*
- Check  $\lambda = M_H^2/2v^2$

6 jets

- requires excellent jet energy measurement
- impossible with a LEP-like detector!

Higgs potential

$$V(\Phi) = -\mu^2|\Phi|^2 + \lambda|\Phi|^4$$

# Jet energy resolution

- Challenge: separate W and Z in the hadronic mode
- E.g.: WW scattering, violates unitarity if no Higgs; irreducible background: ZZ
- Dijet masses in WW, ZZ events (w/o kinematic fit):

# Higgs profile analysis

- Global fit using all measured properties
- SM Higgs or MSSM Higgs?

Coupling	$M_H = 120 \text{ GeV}$	140 GeV
$g_{HWW}$	$\pm 0.012$	$\pm 0.020$
$g_{HZZ}$	$\pm 0.012$	$\pm 0.013$
$g_{Htt}$	$\pm 0.030$	$\pm 0.061$
$g_{Hbb}$	$\pm 0.022$	$\pm 0.022$
$g_{Hcc}$	$\pm 0.037$	$\pm 0.102$
$g_{H\tau\tau}$	$\pm 0.033$	$\pm 0.048$
$g_{HWW}/g_{HZZ}$	$\pm 0.017$	$\pm 0.024$
$g_{Htt}/g_{HWW}$	$\pm 0.029$	$\pm 0.052$
$g_{Hbb}/g_{HWW}$	$\pm 0.012$	$\pm 0.022$
$g_{H\tau\tau}/g_{HWW}$	$\pm 0.033$	$\pm 0.041$
$g_{Htt}/g_{Hbb}$	$\pm 0.026$	$\pm 0.057$
$g_{Hcc}/g_{Hbb}$	$\pm 0.041$	$\pm 0.100$
$g_{H\tau\tau}/g_{Hbb}$	$\pm 0.027$	$\pm 0.042$

*% level precision points beyond SM*

# SUSY Higgs sector

- In the MSSM two complex Higgs doublet fields needed  
 $\Rightarrow$  5 physical Higgs bosons:

$h, H$	neutral, CP-even
$A$	neutral, CP-odd
$H^\pm$	charged

Masses at tree-level predicted as function of  $m_A$  and  $\tan\beta$  but large rad. corrections

$$m_h < 135 \text{ GeV}$$

# SUSY Higgs at LHC

Need to observe the heavier Higgs boson either directly or through loop-effects.

Direct observation at LHC difficult in part of parameter space

# SUSY Higgs Bosons at the ILC

Very clear signal in  $HA \rightarrow bbbb$

drawback: pair production  $\Rightarrow$  mass reach  $\sim \sqrt{s} / 2$

reconstructed mass sum

reconstructed mass difference

Example for  $m_H=250$  GeV /  $m_A=300$  GeV at  $\sqrt{s} = 800$  GeV:

# Determine CP

- Many models have two Higgs doublets
  - $H^+$ ,  $H^-$ , and even  $H$  and  $h$ , odd  $A$

Production angle

*Tau*  
polarization

# Invisible Higgs

- Predicted in many extensions
  - MSSM  $H \rightarrow \chi_1^0 \chi_1^0$
  - New singlets ("stealth Higgs")
- If width not too large
  - Missing mass
  - Deficit in branching ratios
- If width large
  - Invisible at LHC
  - No recoil mass peak
  - But excess of events

*5 $\sigma$  down to BR=2%*

# If there is a heavy (or no) Higgs

- This is physics beyond the Standard Model
- Something **must** be in the loops
- Exploit precision potential of LC (tune energy, polarization,  $\epsilon\gamma$  option)
  - Really nothing overlooked at LHC?
  - Probe virtual effects
- E.g. sensitivity of triple / quartic gauge couplings reaches far into the TeV range

model	LHC $\Lambda$ [TeV]				LC $\Lambda$ [TeV]			
	LL	RR	LR	RL	LL	RR	LR	RL
eeqq: $\Lambda_+$	20.1	20.2	22.1	21.8	64	24	92	22
$\Lambda_-$	33.8	33.7	29.2	29.7	63	35	92	24
ee $\mu\mu$ : $\Lambda_+$					90	88	72	72
$\Lambda_-$					90	88	72	72
eeee: $\Lambda_+$					44.9	43.4	52.4	52.4
$\Lambda_-$					43.5	42.1	50.7	50.7

# Higgs summary

- The Higgs boson (or something taking its role) will be discovered at the LHC.
- Its profile can be fully determined at the ILC with precision.
- This can fully establish - or falsify - the Higgs mechanism by which particles acquire mass in the Standard Model.
- If the Higgs is different from SM expectation, or if there is no Higgs at all, we will obtain important clues to New Physics.

## 3.2. The Cosmological Connection

# Extra Dimensions

- “Solve” the hierarchy problem (gravity scale  $\gg$  electroweak scale)
- Gravity lives in  $4 + \delta$  dimensions,  $\delta$  dimensions curled (radius  $R$ )
- Modifies Newton's law for  $r < R$ , lowers Gravity scale
  - E.g.  $\delta = 2$ ,  $R = 0.1$  mm gives  $M_{\text{Gravity}} = 1$  TeV

# Extra dimensions signature

- Measure the number of extra space dimensions
  - Via single photon production  $e^+e^- \rightarrow G\gamma$
  - polarisation important to suppress  $e^+e^- \rightarrow \nu\nu\gamma$

# Dark matter

- In many models dark matter is a "thermal relic" WIMP
- WIMPs are neutral, weakly interacting, massive particles
- Once in thermal equilibrium, then frozen out due to expansion of the universe
- Calculable density today
- Naturally appear in EW symmetry breaking models
  - Mass 100 GeV or so
  - Copiously produced at colliders

# SUSY Dark matter?

- favoured WIMP candidate:  
lightest SUSY particle (LSP), usually lightest neutralino  $\tilde{\chi}_1^0$
- will be seen at LHC - but is it **the** dark matter?
- To claim dark matter discovery, need to establish model  $\Rightarrow$  annihilation cross section to precisely calculate relic density, match with cosmology

*E.g. mSUGRA:  
Depends on  
slepton mass*

# ...or something else?

- Extra Dimensions, Little Higgs with T-parity,....
- => model independent WIMP search?

## Idea:

- relic density  $\Omega_{dm}$  depends on rate for  $\chi\chi \rightarrow$  SM-particles
- crossing symmetry => rate  $e^+e^- \rightarrow \chi\chi$  !

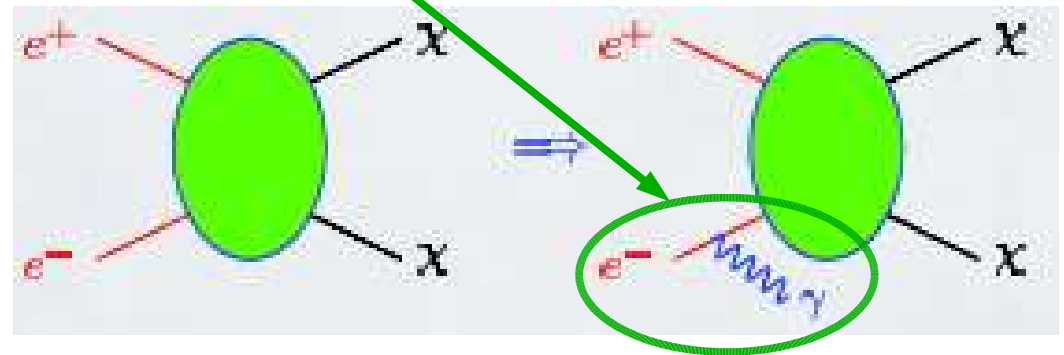

[A.Birkedal et al hep-ph/0403004]

# Model Independent WIMP Search

- consider pair production  $e^+e^- \rightarrow \chi\chi$
- problem:  $\chi$  is invisible in detector!
- trick: use photon radiated off  $e^+$  or  $e^-$
- $\Omega_{\text{dm}} \Rightarrow \sigma(e^+e^- \rightarrow \chi\chi\gamma) \approx 0.1 \dots 10 \text{ fb}$   
 $\sim 50 \dots 5000 \text{ events / 4 years ILC}$

- does this work? **yes!**  
 $\Rightarrow$  compare LEP:  
 $e^+e^- \rightarrow Z^0 \rightarrow \nu\nu (+\gamma)$   
 but: not trivial!
- main background:  $e^+e^- \rightarrow \nu\nu (+\gamma)$

# New Physics

- New Physics - related to electroweak symmetry breaking - is likely to appear below the TeV scale.
- Everything is possible between no new particles and a complete SUSY zoo -> ILC interesting in any scenario!
- Precision measurements provide the clues to the underlying highest scale theories.
- There are clear cosmological questions which can be addressed at the ILC.
- What ever the New Physics might look like, the goal is to....

# Reconstruct fundamental theory

- Example Supersymmetry
  - Precision measurements of SUSY particle masses and couplings
    - E.g. neutralino mass:  $\delta m/m \sim 10^{-3}$
  - Disentangle SUSY breaking mechanism
- Extrapolate to Grand unification scale
- Needs both LHC and ILC highest possible precision
- Maybe only experimental clue to GUT scale physics

*example for mSUGRA model  
But: **not** just an mSUGRA  
parameter fit*

## 4. Summary

- There is a fascinating and compelling **physics case** for a (sub-) TeV  $e^+e^-$  collider running in parallel with the LHC
- The ILC will be ideally suited to map out the profile of the **Higgs** boson - or whatever takes its role - and provide a telescopic view to physics at highest energy scales.
- The **cosmological connection** is evident - we're entering exciting times.
- The **detector** is a challenge. Conceptual detector design choices need to be made in few years time and must be prepared now.
- The **global effort** for the ILC is in full swing!

Thank you!

*Special thanks to my colleagues for  
helping me with their material:  
F.Sefkow, K.Desch and many others*
