

The Large Hadron Collider Project at CERN

Joachim Mnich
DESY

EMBL Forum on Science & Society
15 June 2009

Outline

- **What?**

Introduction

- **Why?**

Physics Motivation

- **How?**

Technological Challenges

- **Where are we today?**

Status and Expectations

The Large Hadron Collider (LHC)

CMS

LHCb

ALICE

ATLAS

CERN

- **European Organization for Nuclear Research**
- **Founded in 1954**
- **20 European Member States**
- **Located close to Geneva across the franco-swiss border**
- **Largest particle physics laboratory world-wide**

The Large Hadron Collider (LHC)

LHC time table:

- **Early 1980's:** first ideas about a multi-TeV proton collider at CERN
- **Oct 1990:** ECFA workshop on LHC in Aachen
- **16 Dec 1994:** CERN council approves the LHC
- **Feb 1996:** approval of ATLAS and CMS
- **Apr 1998:** start civil engineering
- **7 Mar 2005:** first dipole magnet installed
- **26 Apr 2007:** last dipole installed
- **10 Sep 2008:** first circulating beams
- **Oct 2009:** first pp-collisions expected

The Large Hadron Collider (LHC)

- Proton-proton collider in the former LEP tunnel
- Highest ever energy per collision

14 TeV in the pp-system

cf. Tevatron at 2 TeV

- High luminosity (rate of pp-interaction)

up to $10^{34}/\text{cm}^2/\text{s}$

- Conditions as **$10^{-13} - 10^{-14}$ s** after the Big Bang
- 4 experiments:
 - ATLAS**
 - CMS**
 - LHCb** specialised on b-physics
 - ALICE** specialised for heavy ion collisions
- LHC and experiments were constructed in global collaborations

1 000 eV = 1 keV
1 000 000 eV = 1 MeV
1 000 000 000 eV = 1 GeV
1 000 000 000 000 eV = 1 TeV

Overall view of the LHC experiments.

Why? Physics Motivation

Theoretical Particle Physics

▪ Relativity

- **Mass is energy and energy is mass**
- Producing heavy particles requires high energy

$$E = mc^2$$

Albert
Einstein

▪ Quantum mechanics

- **Particles are waves and waves are particles**
- High momentum p (or energy) means smaller wave length

$$\lambda = h/p$$

M. Planck

W. Heisenberg

▪ Uncertainty principle

- **Position and momentum are not defined with arbitrary accuracy**

$$\Delta x \Delta p \approx \hbar$$

▪ ...and God still plays dice

- **Elementary quantum processes are not deterministic, only probabilities are calculable**
- Experiments must be repeated frequently

History of the Universe

13 billion years

5 billion years

First supernovae

1 billion years

Galaxy and star formation

10^{13} seconds

Transparent universe

Formation of atoms

100 seconds

Nucleosynthesis of Helium

Disappearance of positrons

10^{-10} seconds

Formation of protons and neutrons

10^{-34} seconds

Disappearance of antiquarks

Cosmic inflation?

10^{-43} seconds

Quantum gravity epoch

Theory

Standard Model of Particle Physics

- **All known matter consists of four fundamental particle (fermions)**

		Charge		Spin	
Leptons	ν_e neutrino	0		$\frac{1}{2}$	
	e^- electron	-1		$\frac{1}{2}$	
Quarks	ν_μ muon-neutrino	0		$\frac{1}{2}$	
	μ^- muon	-1		$\frac{1}{2}$	
	ν_τ tau-neutrino	0		$\frac{1}{2}$	
	τ^- tau	-1		$\frac{1}{2}$	
	u up-quark	$+\frac{2}{3}$		$\frac{1}{2}$	
	d down-quark	$-\frac{1}{3}$		$\frac{1}{2}$	
	c charm-quark	$+\frac{2}{3}$		$\frac{1}{2}$	
	s strange-quark	$-\frac{1}{3}$		$\frac{1}{2}$	
	t top-quark	$+\frac{2}{3}$		$\frac{1}{2}$	
	b bottom-quark	$-\frac{1}{3}$		$\frac{1}{2}$	

- **There exist 2 copies of each fermion (called generations or families)**
 - Identical, except for the mass
- **Antimatter:**
 - Each fermion has a partner with opposite charge
e.g. the positron (e^+) is the antiparticle of the electron (e^-)

Standard Model of Particle Physics

Fundamental Interactions (forces):

1) Gravitation

- Elementary particles: too weak, not part of the Standard Model

$$F = G \frac{mM}{r^2}$$

2) Electromagnetic Interactions

- Electrostatic Magnetism

$$F = \frac{1}{4\pi\epsilon_0} \frac{qQ}{r^2}$$

- Bind electrons and nuclei to atoms and atoms to molecules

3) Weak Interactions

- Important in certain nuclear and particle reactions, e.g. neutron decay $n \rightarrow p e^- \bar{\nu}_e$

4) Strong Interactions

- Bind quarks in protons and neutrons

Standard Model of Particle Physics

- Fundamental Interactions are mediated by the exchange of particles
 - Spin 1, therefore called bosons
- Fundamental particles are mathematically described by symmetries
 - Local gauge symmetries

Interaction	Mediating Particle	Mass [GeV]	Symmetry Group
Gravitation	?	?	?
Electromagnetic	Photon γ	0	U(1)
Weak	$W^\pm, Z$ Bosons	80, 91	SU(2)
Strong	Gluons g	0	SU(3)

Open Questions

- The Standard Model is very successful in describing phenomena up to a few 100 GeV
- But it leaves many open questions, e.g.
 - Why there are 3 copies of the fundamental fermions?
Related to particle-antiparticle asymmetry in the universe?
 - What is the reason for $U(1) \times SU(2) \times SU(3)$
Is there only one fundamental interaction at high energy?
 - Gravitation?
At high energy 10^{19} GeV gravitation matters
 - **Origin of Mass?**
 - **Dark Matter**
 - ...
- Experiments at the LHC are expected to provide some answers to these fundamental questions

Origin of Mass: The Higgs Boson

- Concept of local gauge symmetries requires massless exchange particles
 - Uncertainty principle:
massive exchange particle
= limited reach of interaction
 - Ok for photon and gluons
 - **Manifestly violated in case of W & Z Bosons!**
- Solution is Higgs mechanism
 - Vacuum is filled with a field
 - Gives mass to W,Z bosons and fermions
 - Requires existence of the Higgs boson
 - **Important: its mass must be less than 1 TeV**
LHC will definitely decide on this issue!

Dark Matter and Supersymmetry

■ Astronomy:

- Only about 5% of our universe are made of known matter!
- $\approx 20\%$ dark matter
- $\approx 75\%$ dark energy

■ Theory of Supersymmetry:

- Symmetry between force and matter particles
- Predicts a mirror world of new particles (a shadow world like anti-matter)
- Solves many of the open questions
- Contains a particle for Dark Matter

How?

Technological Challenges

2000: „Concept“ of the CMS tracking detector

Sergio Cittolin

A Collider for the Terascale

■ Electron-Positron Collider

- Like DORIS & PETRA at DESY or LEP at CERN
- Point-like particles
- But limited in energy by synchrotron radiation

■ Proton-(anti)proton collider

- Higher energy reach limited by magnet bending power
- But much harder for experiments

Challenges for the LHC: Magnets

- Superconducting dipole magnets to keep 7 TeV protons on a circular path ($r \approx 3$ km)

$$|B| = 8.33 \text{ Tesla}$$

- 1232 dipole magnets needed each is 15 m long (+ quadrupoles, sextupoles, etc.)
 - 1.9 K operating temperature
 - Supraliquid Helium
 - Largest cryogenic facility in the world
- Quench protection
 - Stored energy in one dipole: 8 MJ corresponds to a 40 t truck at 50 km/h

- LHC dipole design incorporates reversed field for oppositely rotating proton beams

LHC Dipoles

- Around 1999: construction of dipoles start

LHC Dipoles

Dipoles in the LHC Tunnel

Cryogenics

- First cool down of an LHC sector (> 3 km) in April 2007
- 1.9 K: colder than the universe

Challenges for LHC Detectors

- Protons are composite particles
 - Bags filled with quarks and gluons
 - Quark-quark and gluon-gluon collisions are the fundamental processes
 - Screened by interactions of other quarks & gluons
- LHC is filled with $2835 + 2835$ proton bunches
 - Collisions every 25 ns
40 MHz crossing rate
- 10^{11} protons per bunch
 - 25 pp interactions per crossing (pile-up)
 - Each bunch collision produces ≈ 1600 charged particles

A Collision Producing a Higgs Boson

- with 25 pile-up interactions

- Remove low energy tracks ($p_T < 25 \text{ GeV}$)
- $H \rightarrow ZZ \rightarrow 4 \text{ muons}$

- Identify each track
- Reconstruct every track

requires a highly granular detector
takes a lot computing power

Example: CMS Tracking Detector

- Silicon strip detector

- 16000 such modules built
- 220 m² of silicon surface (almost a tennis court...)
- Largest silicon detector ever built

A Dream Becomes Reality...

Looking for a Needle in a Haystack

- Protons are large particles
 10^{-15} m diameter
- Not pointlike as e.g. electrons
(diameter $< 10^{-18}$ m)
- Huge proton-proton interaction rate at the LHC
 - **10^9 per second**
 - **10^8 per second in initial phase**
- However, most interesting processes are rather rare
- E.g. about 1 Higgs boson per minute will be produced

Finding the Higgs Boson

- Online trigger
 - Only a tiny fraction of the collision can be stored for detailed inspection
 - Interaction rate $\approx 10^9$ events/s
 - Max. record rate ≈ 100 events/s event size ≈ 1 MByte $\Rightarrow$ 1000 TByte/year
 - **Trigger rejection $\approx 10^7$**
- Collision interval is 25 ns corresponds to 5 m cable delay
- Trigger decision takes a few μ s (1st level)
 - $\Rightarrow$ **store massive amount of data in front-end pipelines**
 - $\Rightarrow$ **massive parallel computing**

The Worldwide Computing Grid

- 1000 TByte/year and experiment are still huge + simulation + calibration + reconstruction + ...
- Grid Computing a world-wide computing centre

Principle of Particle Physics Detectors

■ Slice through the CMS detector

Magnetic field to bend charged particles

ATLAS and CMS

- ATLAS and CMS are the two large multi-purpose detectors at the LHC
- Each collaboration counts about 2500 scientists & engineers from about 40 different countries

International Collaboration

International Collaboration

- Brass casings of decommissioned shells of the Russian Northern Fleet

- Converted to brass absorbers for the CMS calorimeter

ATLAS: A Toroidal LHC ApparatuS

ATLAS with inner Detectors

CMS: Compact Muon Solenoid

CMS

Beampipe in CMS

Comparison ATLAS and CMS

	ATLAS	CMS
length	≈ 46 m	≈ 22 m
diameter	≈ 25 m	≈ 15 m
weight	≈ 7000 t	≈ 12000 t

LHCb

- Experiment to address the question of matter-antimatter asymmetry

ALICE

- Experiment addresses new state of matter: the quark-gluon plasma

- Heavy ion collisions, eg. Pb-Pb

Where are we today?

Status and Expectations

- First circulating beams on September 10, 2008

LHC Accident

- Major accident on September 19, 2008
 - Bad connection between 2 magnets (resistance $\gg 1 \text{ n}\Omega$)
 - Heat load $\approx 10 \text{ W}$ cannot be cooled away
 - Thermal runaway
- Quench protection of magnets worked well
- But light arc between magnets
 - Destroyed a Helium vessel
 - 2 tons of He effused
 - Shock wave in tunnel

Damage

**53 magnets inspected,
repaired & reinstalled**

Plans

- Improve protection systems
- Restart LHC in September 2009
- First collisions in October 2009
- Operation until end 2010
 - reduced energy (5 TeV)
- Detectors are ready and preparing for data taking with cosmic rays

Possible Higgs Discovery in 201x

$H \rightarrow \gamma\gamma$:

$m_H = 130 \text{ GeV}$

$\sigma_{mH} \approx 1 \text{ GeV}$

large combinatorial background

background subtracted

$H \rightarrow ZZ \rightarrow 4\mu$:

$m_H = 200 (300, 500) \text{ GeV}$

Note the increasing signal width

Supersymmetry

- LHC will eclipse previous experiments and chart new territory in the parameter space
- Example: discovery reach as function of luminosity and model parameters which fix the mass scale of SUSY parameters

LEP exclusion

Summary

PHYSICS AT THE TERASCALE

- LHC is one of the largest scientific endeavours ever undertaken
- 25 years of preparation involving thousands of scientists all over the world
- Likely to be exploited for decades
- Results will change our view of the universe

An aerial photograph of the CERN facility in Geneva, Switzerland. A large red circle is drawn on the image, highlighting a specific section of the LHC tunnel. The surrounding area includes various buildings, roads, and green spaces.

- **Backup slides**

Vision

- Revolutionary advances in understanding the microcosm
- Connect microcosm with early Universe

Particle Physics at the **Energy Frontier** with highest collision energies ever will change our view of the universe

A Collision Producing a Higgs Boson

Higgs Boson Decay

Higgs couples proportional to masses

⇒ preferentially decaying into heaviest particle kinematically allowed

Branching ratio versus m_H :

- **Low mass ($115 < m_H < 140$ GeV)**
 $H \rightarrow b\bar{b}$ make up most of the decays
problem at the LHC because of the huge QCD background !
- **Intermediate ($140 < m_H < 180$ GeV)**
 $H \rightarrow W W$ opens up
use leptonic W decay modes
- **High mass ($m_H > 180$ GeV)**
 $H \rightarrow Z Z \rightarrow 4$ leptons
golden channel!
